The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the District of West Bromwich County Court (Circuit No 25) Applications should reach the Private Secretary, Home Office, not later than Feb 4th

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Crickhowell (Brecknockshire) Newton Mearns (Renfrewshire), St Columb (Cornwall), and Shefford (Bedfordshire)

Births, Marriages, and Deaths.

MARRIAGES

LOUGHBOROUGH—MATHER.—On Jan. 12th in London, Dr G Trevor Loughborough of Bentinck-street, W, to Mrs B Vanstone Mather, of Ashley gardens, S W.

DEATHS

JONES —On Jan 10th, at a London nursing home, William Percy Jones, M.D, late of Brent, South Devon.

LARKIN —On Jan 13th, at his residence Craven House, Grove Park, Kent, Frederick George Larkin, F R C S Eng (honorary) in his 80th year

OWEN —On Jan 14th, in Paris, Sir Isambard Owen, M.D, F R.C P, D C L, LL D &c., Consulting Physician to St George's Hospital, aged 76

PASMORE.—On Jan. 12th, at Chelsham House, Warlingham Surrey Edwin Stephen Pasmore, M.D M.R.C P, Medical Superintendent, Croydon Mental Hospital

SHAW —On Jan. 14th after a short illness Thomas Clave Shaw, M.D F R.C P, M.R.C S of Claremont Lodge, Cheltenham, and Queen Anne-street London.

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births Marriages, and Deaths

INDEX TO "THE LANCET,"
VOL. II, 1926

THE Index and Title-page to Vol II, 1926, which was completed with the issue of Dec 25th, is now in preparation A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

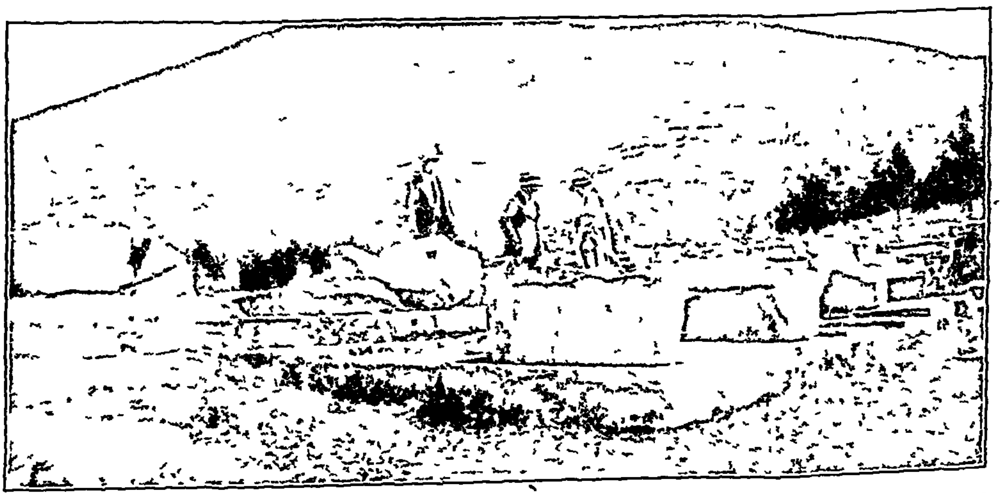
MEDICINE IN ANCIENT GREECE

Sir James Berry (the President) and Lady Berry received the guests at a social evening held by the Royal Society of Medicine on Jan 17th, when Prof A W Sheen gave a short address on Greek medicine

He began by tracing the mythical career of Æsculapius, the God of Medicine, who was depicted a commanding figure, leaning upon his serpent-entwined staff He was a pupil of Cheiron, the kindly centaur, but unlike his companions, who trained as warriors, Æsculapius dug up healing herbs and learnt their virtues So proficient in healing did he eventually become that Pluto feared the underworld would lose its population and killed Æsculapius by the hand of a Cyclops Apollo, his father, was angered and Æsculapius was made a god Prof Sheen illustrated the story with lantern slides showing the daughters of the God, Hygeia and Panacea, and a group of suppliants approaching the God and his family The sacred serpent is a feature of all ancient statuary and is still the badge of medicine

In Homer references to medicine are frequent Podalirius and Machaon were warriors as well as physicians and brought ships and men to the war "Full thirty sail the sparkling waves divide, which Podalirius and Machaon guide " They were held in high esteem, for "a wise physician skilled our *wounds to heal, is more than armies to* the public weal," and, when Machaon was wounded there was great consternation amongst the Greeks for, said one, "a physician is worth a host of other men" A woman who might be described as the first trained nurse in history—"Hekamede of the beautiful hair"—attended Machaon in Nestor's tent, gave him a stimulating drink and dressed his wound Malaria and rickets are indicated in Homer, also the "drink of oblivion" (probably opium), but references to wounds predominate, for the gods could suffer from injury but not diseases A beautiful vase-painting shows Achilles bandaging the arm of the wounded Patroclus, from which it is evident that he was an amateur in the art

Fig. 1.



The Temple of Æsculapius at Epidaurus, from a photograph by Mr Laming Evans The visitors are the President of the Royal College of Physicians of London, Lady Bradford, and Sir Hector Mackenzie

Solon, the great law-giver (B C 638) described physicians as follows "Others, who have the profession of Paion, god of medicines, are the physicians, neither on their labours is any certain issue fixed Often from a trifling pain comes great suffering, and no man can alleviate it by administering soothing drugs But sometimes, when a man is afflicted with disease fell and fierce, the physician by touching him with his hands at once makes him whole"

Clinics and Temples

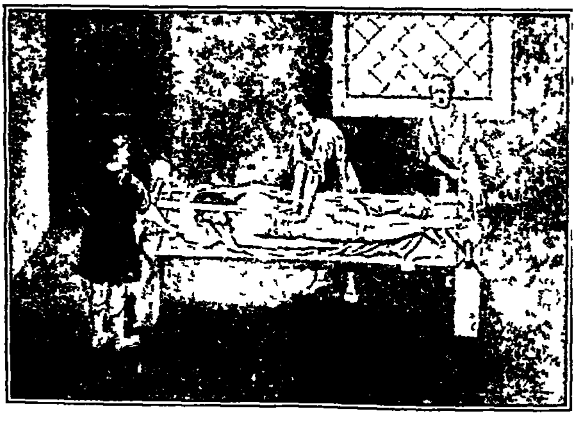
Describing the development of Greek medicine, Prof Sheen drew attention to the Iatria or surgeries, and showed pictures illustrating their work and the instruments used in them One vase-painting shows the medical practice, the physician is letting blood, a patient smells a flower, another awaits bleeding, whilst other patients are a man with bandaged leg, a dwarf, and a man leaning on a staff He quoted Aristophanes' description of physicians "Lazy, long-haired, foppish individuals with rings and carefully polished nails" With orthodox physicians were mixed up quacks of various kinds, human needs being served and human weaknesses exploited in the manner of to-day

Of the numerous health temples that at Epidaurus was described, and a photograph of the ruins was shown (Fig 1) Beautifully situated in the pure air of the hills the many buildings with open air wards permitted development of rational treatment alongside priestly methods The Temple of Æsculapius contained the great gold and ivory statue of the God, whilst in the "pump room" were two paintings, one of Methe (drunkenness) looking through a wineglass, the other of Eros (love) laying aside his quiver for the lyre—a less dangerous weapon Perhaps the paintings were there as salutary warnings to the patients Deciphered tablets from the walls of the wards show most remarkable cures Heraieus of Mytilene, for instance, had no hair on his head, the God applied an ointment and next morning *the head was thickly covered with hair* Another inscription indicates the treatment of dropsy by cutting off the patient's head, holding him by his heels and letting the fluid run out after which the head is put on again Sane method of treatment undoubtedly developed in spite of such absurdities

Hippocratic Period

The great period of Greek medicine was reached in th time of Hippocrates, "the father of medicine," who live *in the latter half of the fifth century* B C Hippocrates wa a rational clinical physician whose work has endured for al time Prof Sheen described the School of Hippocrates th Health Temple on the Island of Cos, situated 400 feet u on a south-facing hill, and in its general arrangement muc resembling Epidaurus He quoted many of the saying o Hippocrates "And this I know that to the human bod it makes a difference whether the bread be fine or coarse" is evidence of a modern opinion The Hippocratic facies "A sharp nose, hollow eyes, collapsed temples, the ea cold, contracted and their lobes turned out, the skin abo the forehead being rough, distended and parched, t colour of the whole face being green, black, livid or le coloured," gives a very true description of impendi death, and may be compared with Shakespeare's dy Falstaff "His nose was as sharp as a pen and he babbl of green fields" Cheyne Stokes breathing was th described "The respiration throughout, like that of person recollecting himself was rare and large," whilst t duties of a physician were summarised as follows "T physician must be able to tell the antecedents, know t present and foretell the future—must meditate these thin and have two special objects in view with regard to diseas namely, *to do good or to do no harm* The art consists three things—the disease, the patient, and *the physicia* The physician is the servant of the art and the patient mu combat the disease along with the physician" Arrang ments for operation, said Prof Sheen, were given in gre detail by Hippocrates and his school The *instruction* th "the robe in a neat and orderly manner is to be thrown over the elbows and shoulders equally and proportionately," suggested a pleasing contrast to the blood-bespattered old frock coat of not many years ago, whilst the following injunction to silence was apposite to day "Those about the patient . must hold the rest of the body steady, in silence, and listening to the commands of the operator" The treatment of fractures was quite modern Besides splints—sometimes recommended only to avoid blame from the common people—waxed bandages were used and readjusted on the third and seventh days "The model by which we judge the part be properly set is the sound part of the same name or the part which is its pair," which sound advice is sometimes neglected nowadays

FIG 2



A Hippocratic bench

[*Wellcome Historical Museum* (copyright)

The history of the Bench of Hippocrates through the ages, continued Prof Sheen, is quite romantic It was a "proper wooden machine with all the mechanical powers applicable in cases of fractures and dislocations For this purpose it will be sufficient to possess a board in length, breadth and thickness resembling the quadrangular threshing-boards made of oak" (Fig 2) A refectory table discovered in an old Italian monastery was found on "dissection" to be a Bench and is now in the Wellcome Historical Medical Museum, London The Hawley table is the Bench's modern counterpart

The celebrated aphorisms of Hippocrates—412 in number —were next alluded to "Life is short and Art long, the occasion fleeting, experience fallacious and judgment difficult," and another, "Where sleep puts an end to delirium it is a good symptom" were given as evidence of their quality The "succussion splash" was thus described "You will place the patient on a seat which does not move, an assistant will hold him by the shoulders and you will shake him applying the ear to the chest so as to recognise which side the sign occurs" The attitude of Hippocrates towards epileptic fits well illustrated his rational mind "It is thus with regard to the disease called Sacred, it appears to me to be nowise more divine nor more sacred than other diseases, but has a natural cause from which it originates like other affections Men regard its nature and cause as divine from ignorance and wonder because it is not at all like to other diseases" The Oath of Hippocrates showed his high ideals of work and service Not even casual conversation is to be repeated "Whatsoever I shall see and hear in the course of my profession, as well as outside my profession in my intercourse with man, if it be what should not be published abroad, I will never divulge, holding such things to be holy secrets"

Conclusion

Prof Sheen quoted what he called a truly Hippocratic maxim from Plato who says—through the mouth of Socrates in the Charmides—"that where there is eye trouble you must treat the head and you cannot treat the head without treating the whole body" He referred to Herophilus (B C 300) whose name is preserved in the term, Torcular Herophili, and to his wonderful fragment, "Science and Art have equally nothing to show, strength is incapable of effort, wealth useless, and eloquence powerless if Health be wanting" He concluded his address with his favourite Hippocratic sentence "Where the love of man is, there is also love of the Art"

HEALTH AND SANITATION IN IRAQ

IN the recently published report by H M Government to the Council of the League of Nations on the administration of Iraq for the year 1925, considerable space is devoted to medical and sanitary matters

Distress Caused by the Severity of the Weather

The winter of 1924–25 was marked by its extraordinary severity In Baghdad until the middle of February the temperature fell frequently at night below freezing point, in the north and in the highlands of the eastern provinces snow and extreme cold devastated the flocks, and if on the southern desert border the cold was less severe, both flocks and shepherds were less accustomed to bear it, and suffered great distress Very little rain fell, and that which occurred during the frost was useless to cultivators The spring harvest was, in consequence, exceptionally bad, and the summer harvest was equally affected by lack of water in the rivers for irrigation purposes Already, in February, the Council of Ministers agreed to exempt from customs duties imported wheat, barley and flour, in view of the alarming high prices which had been reached But in the north the situation went from bad to worse owing to the ravages of locusts, and by the autumn the shortage of grain was so disastrous that steps for the relief of an almost starving population were necessary Seed grain for the ensuing harvest had also to be provided in many parts of Iraq, and loans issued to needy cultivators

Health Services

During the year the health service has continued its steady progress and development, free for the first time in its history from the fear of experimental budget reductions, and happy in the thought that its organisation and scope of work appeared to be at last on an accepted basis The service has fortunately been free from anxieties in the shape of severe epidemics or other abnormal outbreaks of disease amongst the population During 1925 the service maintained 18 hospitals and 53 dispensaries in the different liwas of Iraq The total number of beds in all the hospitals in the country is 1170 The Maude Memorial Hospital at Basra has been completed, and all its departments are now functioning with the exception of a ward for women which it is hoped to furnish and staff in the new financial year

Infectious Diseases

There has been nothing abnormal in the number of cases reported of the various infectious diseases with the exception of plague, of which only 20 cases were noted This is by far the lowest figure since the British occupation of the country The reason for this very low incidence of plague was undoubtedly the cold weather of the winter of 1924–25, which killed off a large proportion of the animal population and amongst which the rat population suffered very severely An additional favourable factor was the effect of the cold weather on the fleas, conditions being very unfavourable for their breeding in the early spring, the season when they are usually most prevalent It would be very unwise to deduce that this very low incidence of plague will tend to continue, and, as a matter of fact, at the moment of writing this report, conditions are such that it appears probable 1926 will be a bad plague year

An increase of small-pox is accounted for by epidemics amongst tribes in the Amara, Kirkuk and Muntafiq liwas

Enteric group diseases appear to be definitely on the increase during the last five years Reported cases are diminishing in Basra, while they are increasing in other areas The increasing incidence of measles and mumps within the period is of no particular importance, notification is better amongst the tribes The increase of tuberculosis is apparent only, for example, 147 cases are reported this year from Karbala compared with 95 in 1924, and 8 only in 1923 Re reporting of old cases and the personal factor of the reporting medical officer or general practitioner are the most probable cause of the increase

The table of patients treated in health service institutions in the various liwas shows that the institutions are doing very good work, and that there is a steadily growing appreciation of the facilities provided

Prostitution

A form of control exists in all towns where recognised prostitutes practise, and there is no doubt that where the powers of control are honestly enforced, a benefit to the public results, though the actual benefit is impossible to estimate by any statistics that can be obtained as to the incidence of venereal disease amongst the general public Under present conditions the problem of prostitution is impossible of solution in Iraq, the chief obstacle being that in Iraq, as in the majority of eastern countries, once a woman has taken up, or been forced into, prostitution she has no means of escape from it, since there are practically no occupations in which an independent woman can earn an honest living Compulsory prohibition of prostitution, or enforced cessation from practise of infected prostitutes if efficiently enforced, would be a sentence of death to thousands of these women, unless the Government could provide institutions for their maintenance for the rest of their lives

Public Health

The whole of the institutions of the Health Service play their part in the combat of epidemic and endemic disease With the exception of the liwas of Basra and Baghdad, the health authorities of each liwa is the civil surgeon who has charge of all institutions, is also responsible for all sanitary measures for the combat of infectious disease, and is the adviser on sanitary matters to all municipalities in his area The Port and Liwa of Basra are under the sanitary control of a specialist health officer, and the epidemiologist attached to the headquarters of the Health Directorate has special sanitary control over the Baghdad Liwa in addition to his general duties, which also include control of the pilgrim traffic These arrangements work well in practise, and Iraq may be considered as possessing an efficient sanitary organisation for the combat of infectious diseases The only assistance that the country requires from outside sources in this connexion is the establishment of research laboratories for the study of malaria bilharzia, and other endemic diseases of the country, such as have been provided by the Rockefeller foundation in other parts of the world

Pilgrim and Corpse Traffic

The control of pilgrims and of the transit of corpses for burial in the holy cities of Iraq has been greatly strengthened The Corpse Traffic Law was passed at the end of 1921, and came into full operation in March, 1925 This law provides for examination of corpses at the frontier of Iraq by quarantine officials, the issue of transit passes, and the checking of these passes by quarantine officials at the place of burial Prior to the operation of this law a large amount of corpse smuggling was taking place, the corpses once within the country passing as local corpses and being free from transit fees or other interference The new system, by which special transit passes for local corpses are also required, renders it impossible for corpses to be buried at the holy cities without production of a pass or payment of transit dues A large amount of smuggling is still taking place but this now only results in a loss of revenue, without loss of sanitary control, since all corpses in transit are now inspected whether of foreign or local origin The numbers of foreign and local corpses for which transit permits were issued since April, 1925, were 4124 and 12,178 respectively The issue of passes for pilgrims has also been taken over this year by the Health Service at the Quarantine Station of Khanaqin and the number of pilgrims examined and given passes at this station during 1925 was 18,199 (15,318 males and 2851 females) It will be observed from these figures that the pilgrim traffic is resuming its normal figures, this is due to more stable conditions in Persia Owing to troubles in the Hejaz and in Syria no pilgrimage to Mecca took place from Iraq either by the sea or overland routes

Medical Education

The Government maintains a school of pharmacy and provides facilities for the training of midwives, nurses, dressers, and vaccinators It is a matter for regret, however, that its finances have not as yet allowed it to institute a school of medicine for the training of doctors Skilled personnel exist in the Health Service who could undertake all necessary professional duties, special institutions exist which could be used for educational purposes, and the cases treated at the Royal Hospital in Baghdad afford magnificent facilities for the instruction of medical students The sole obstacle to the establishment of a school is the question of a suitable building for its accommodation, which must be in a site immediately adjacent to, if not in the grounds, of the Royal Hospital

---

ORDEAL BY BATTLE

Two correspondents have written to correct and expand a misleading historical reference in a recent article on "Standing Mute of Malice" It was there stated that Abraham Thornton had recourse to the obsolete legal process of ordeal by battle in 1817 "and thus evaded the consequences of a conviction for murder" Thornton was protecting himself against the risk—some might call it almost the certainty—of a conviction but he was never actually convicted His story was summarised in THE LANCET of April 3rd, 1926, in a review of Sir John Hall's volume in the 'Notable British Trials" series Thornton was acquitted at Warwick Assizes, but public opinion was so sure of his guilt that an obsolete procedure (appeal of murder) was invoked to obtain a re-trial To this he replied with his offer of battle Both these ancient processes were abolished by the Statute 59 Geo III c 56

PUBLIC HEALTH IN BRITISH HONDURAS

IN his report on this Colony for the year ended Dec. 31st, 1925, Mr C Douglas-Jones, Colonial Secretary, states that the estimated population is 47,893 (23,683 males and 24,210 females) The birth-rate for the year worked out at 37 27 per 1000 of the estimated population The deaths corresponded to a rate of 21 38 per 1000. The principal causes of death, in order of frequency, were diseases of the digestive system, diseases of the circulatory system, and diseases of the respiratory system. There were 29 deaths from malaria, 6 from influenza, 50 from pulmonary tuberculosis, and 21 from enteritis An outbreak of dysentery occurred in the lunatic asylum, in which 26 cases were treated, with 8 deaths Malaria, while being prevalent, was of a mild type, there being only 29 deaths certified by medical practitioners as due to this cause Pulmonary tuberculosis seems to be on the increase, both in the town of Belize and in the districts Symptoms of hydrophobia were shown by dogs in Belize in April, but it was not until June that a fatal case of rabies occurred The total number of deaths from this cause was four A muzzling order was introduced, and the shooting of unmuzzled dogs within certain hours had the desired result of exterminating all stray dogs and checking the spread of the disease Anti rabies vaccine has been used with success The climate of British Honduras compares favourably with that of other tropical countries with small European population Europeans leading a normal life and taking common precautions find the climate pleasant and healthy The highest rainfall was as usual at Punta Gorda in the Toledo district, which had a total of 207 68 inches and 221 days on which rain fell The lowest rainfall was at Corozal, which had a total of 34 12 inches At Belize the rainfall was 86 01 inches The hottest day was May 25th, on which the thermometer registered 91 5° and the coldest day was Nov 24th, when it registered 50 5° F

HERPES AND VARICELLA

To the Editor of THE LANCET

SIR,—The following case is of interest in connexion with the alleged relation between herpes and varicella On Dec 20th, 1926 a gardener developed herpes zoster ophthalmicus On Jan. 5th, 1927, his three children, two girls aged 8 and 9 years respectively, and a boy aged 5, all showed definite chicken-pox The source of this outbreak of varicella could not be traced apart from the above-mentioned herpes The time between the herpes and chicken-pox is sixteen days The children were seen by me at one of the school clinics

I am, Sir, yours faithfully,
FREDERICK W GAVIN, M B, Ch B, D P H,
Asst M O, Surrey C C
Jan 18th, 1927

AN IRRADIATION CLINIC

A REPORT by the Health Committee of the Northamptonshire County Council gives a preliminary account of some results obtained with an installation for ultra-violet radiation recently provided at the Wellingborough Dispensary, primarily for the treatment of lupus A total of 25 patients have been in attendance for irradiation, 12 were suffering from lupus and allied conditions, 10 were pre-tuberculous and had been selected for treatment on account of general debility, failure to gain weight, or wasting, and 3 were suffering from pulmonary tuberculosis The whole group of cases exclusive of those suffering from pulmonary tuberculosis, has shown a total gain in weight of 65 lb and a loss of 1 lb as compared with a gain of 12 lb and a loss of 15 lb in the three months before this treatment was started All the cases of lupus show marked improvement A discharging tuberculous abdominal sinus of three years' duration is soundly healed, a case of lupus pernio of three years duration is healed and normal, and two cases of discharging tuberculous glands in the neck associated with gross keloid are practically healed and promise good cosmetic result A case of facial and intranasal lupus has so far improved that the face is normal and the nasal mucous membrane reveals no signs of disease, a case of extensive and severe lupus erythematosus has remarkably improved, whilst another case of ordinary lupus is soundly healed and has gained 5 lb in weight It was noticed that associated conditions such as boils and blepharitis cleared up quickly when their tuberculous lesions were treated by irradiation The pre-tuberculous children gained in appetite and general brightness and the only cases in which there has been little or no improvement are those of pulmonary tuberculosis It is considered too early, however, to assess the value of irradiation in this disease

---

FORTY-THREE YEARS A CORONER—*On Jan* 15th Mr S Brighouse, who is 77, completed 13 years as coroner for South-West Lancashire He has conducted over 20,000 inquests, including the famous Maybrick inquiry

Hastings Lecture

[ABSTRACTED]

ON

CANCER AND HOW TO FIGHT IT

Delivered before the British Medical Association on Jan 24th, 1927,

BY SIR BERKELEY MOYNIHAN, BART, K C M G, C B, M S LOND,
SENIOR SURGEON, LEEDS GENERAL INFIRMARY, PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

A SURVEY of the progress of medicine during this century shows that we are, little by little, but very surely, obtaining control over certain diseases which were formerly the plagues of mankind In comparison with them cancer not only shows no decrease, it is actually gaining ground In the last 20 years the general death-rate has fallen by 32 per cent, the infant death-rate by 45 per cent, the tuberculosis death-rate by 38 per cent, while the cancer death-rate has increased by 20 per cent In the last 70 years the mortality from cancer has increased five-fold.

Attempts have been made to explain this increase (*a*) by consideration of the fact that the average expectation of life having increased, a larger number of people live to the cancer age, and (*b*) by ascribing it to increased accuracy of diagnosis To some extent both explanations are true But the average duration of life is longer chiefly because of the lower infant mortality Dr Leonard Hill says .—

> "The expectation of life has gone up for infancy but not for the period of late middle age There is no problem of what we are to do with our grandfathers, they are living scarcely any longer than they did 50 years ago"

And if we pay regard to those cases in which diagnosis can never have been difficult, because the disease was near the surface and easily seen or felt, we find that the second argument is not sustained For example, in cancer of the tongue there has been an increase of 39 per cent, and in cancer of the breast of 28 per cent in the last 20 years It must also be remembered that some few diseases called cancerous in other days are now known to be simple

BELATED SURGICAL TREATMENT

This increased mortality from cancer, chiefly in the alimentary canal, has occurred despite the fact that more people than ever are being cured of cancer The operations practised to-day are more frequent, of greater extent, of greater safety, and attended by a larger measure of permanent relief from the disease than was the case 20 years ago Montaigne thought the doctor among the most fortunate of beings, because the sun shone upon his successes, while his failures were buried in the tomb But this is not altogether true We hear of deaths from operations, of recurrence of cancer after its removal, we hear little even from the rescued of their *freedom from this disease*

If it is true, as it is indubitably true, that permanent relief from cancer is being secured by our present *methods* in large numbers of cases, the question naturally arises as to why this is not more often possible We are all a little to blame Medical men are sometimes, though I am glad to think not very often, inclined to watch the earlier phases of this disease, *especially* when attacking internal organs, until it is certain that the condition is malignant The certainty of diagnosis is often the *certainty* of death If we wait until we know, we wait until we cannot cure And the public is in part to blame, for among them *there is great ignorance* of the possibilities and the achievement of surgery, and ignorance is the parent of unbelief The patient who *discovers*, say, a tumour in the breast says to herself "There is something wrong here, it may be cancer, if it is cancer I must undergo an operat*ion*, *if I* do I may die, if I survive the disease may come back, if it returns I must submit once again to operation with all its risks—even then the disease may recur; it is a hopeless and depressing prospect I had better not mention the fact of the lump" At last she submits to a rescue operation when the chances now are all against the surgeon

Unhappily, it is not very infrequent for the delay to be encouraged by the wasteful trial of other methods The "cancer curer" is still a curse in the land, and the most pathetic credulity as to his claims is shown by people who should know better Cancer never yet was cured by the quack, but infinite harm has come to patients from the delay which foolish, impotent, and pernicious practices have involved

EDUCATION AND FEAR

Cases of cancer may conveniently be divided into (1) those in which the growth is lying either on or near the surface of the body, or is attacking organs or parts of organs which can with no great difficulty or danger be removed, and (2) those in which the growth is relatively inaccessible, lies out of sight, cannot be felt, and only reveals its presence by symptoms, or after examination by X rays In these cases an operation may be difficult, impracticable, or even impossible

It is obvious that two methods of attack must be followed In the first place we must so instruct the public and educate ourselves that those cases of cancer in which complete eradication of the disease is surgically possible shall be recognised and treated at the earliest moment The operations now practised have almost reached their limits not only in their extent and in the safety with which they can be performed by expert surgeons, but also in respect of the pain or discomfort they inflict We can make surgery safe and even more successful, not by strengthening the arm of the surgeon, but by enlisting the help of the patient; by encouraging him with the knowledge that accessible growths are capable of complete removal, with small risk, and with permanent freedom from recurrence, if only they can be reached in time And in the second place we must carry out all manner of research so that inaccessible cancer shall also be treated with success or even prevented.

With regard to the education of the public there are certain disadvantages, some fanciful, some real It is said that if we "talk cancer" we shall make people "think cancer" We hope that is true We do not wish the public to "forget cancer" For cancer is an unforgiving enemy, and once he has settled upon his victim he never for one single moment ceases to grow, and the sooner you confront your foe the better for you and the worse for him It is said that we shall increase fear That I firmly believe is impossible If we can help the public to learn that it is not cancer, but ignorance with regard to cancer, that is in part responsible for their horror of it, and if we can assure them that cancer under certain conditions and when attacking certain organs is capable of complete removal with permanent freedom from a return of the disease, shall we not be able to diminish or even to banish this horror? Fear should be the fear of delay; the fear lest a simple disease may become cancerous, the fear lest a local and, therefore, curable cancer should increase until it becomes generalised and incurable Knowledge will bring freedom from fear

Two consecutive events must be secured: the awakening in the patient's *mind of a need to consult* the doctor, and action by the doctor, who, in turn, seeks aid from the surgeon. Unless, therefore, a patient knows something of the antecedent conditions of cancer, of its early manifestations, of the importance of early treatment, how is he to realise *that a medical* man should be consulted without the delay of one single day?

WHAT THE PUBLIC SHOULD BE TAUGHT

The following are some of the truths it is important for the public to know —

(1) Cancer is always at first a local disease, spreading by direct extension from the spot first affected It

is often supposed that cancer is a "blood disease"—that the blood is contaminated and that the local evidence of this is the nodule or the ulcer, recognised as cancerous All knowledge we possess refutes this view

(2) Cancer chooses to attack a diseased rather than a healthy organ This involves the necessity for us all to pay attention to health and to do all we can to keep fit. The majority of people, it may be said, commit suicide

(3) The occurrence of cancer is influenced by antecedent conditions Chronic irritation is a definite precursor of cancer, as is seen especially upon exposed surfaces

(4) The occurrence of cancer, so far as we know, is uninfluenced by certain factors sometimes regarded as "causes"—

(*a*) There does not appear to be any *hereditary predisposition* to cancer The fact that one person in seven over the age of 30 dies from cancer implies that within the limits of slight variation from this normal the incidence in any family may appear to be unduly heavy Probably few families of ordinary size escape cancer in three consecutive generations The work of Miss Maud Slye upon mice appears to show that a tendency to the development of cancer can be engendered by special breeding, but I cannot recognise any similar liability in man.

(*b*) Cancer, so far as we know, is not caused by any *special food* or foods, nor by any absence of special foods It is true that excessive indulgence in food when little or no exercise is taken will steadily and insidiously depreciate the general health, and that in such circumstances of lessened resistance a person may more easily fall a victim to cancer as to other diseases Various articles of diet have been impugned—tomatoes, fresh meat, salt, and many other—but there is no evidence that would satisfy a scientific mind that these or any other articles of diet, in excess or in abstinence, play any specific part in causing this disease So far as we know, no change in the natural history of a malignant growth has ever been observed by competent authorities to result from such dietetic control in an indisputable case of carcinoma

(*c*) There is at present no sufficient proof that *cancer-houses* or cancer-districts exist, though further inquiry may well be conducted to resolve this question

(5) The disease is neither infectious nor contagious

(6) In the early stages cancer rarely causes pain In tumours of the breast, for instance, no pain, as a rule, is caused until the skin is involved, the lump is discovered by accident, and little regard is paid to it because it causes no inconvenience or discomfort The truth that in women over 35 years of age a lump in the breast is malignant in three cases out of four needs all the repetition and emphasis that can be given to it The silence of some forms of growth in the stomach and the rectum is notorious, and in the alimentary canal it is often obstruction rather than discomfort that first attracts attention In cases of cancer, ill-health, anæmia, lassitude, distaste for food, and loss of weight are often regarded as the symptoms without which a diagnosis may hardly be made, but the existence of carcinoma is compatible with perfect health, and there may even be a gain in weight and a remarkable feeling of vigour and strength

(7) While the disease is local and when the growth is accessible cancer is curable While the disease is local the complete eradication not only of the part immediately involved, but of all the adjacent parts which are most likely to be first implicated in its extension would also cure the disease In a large number of cases, however, the growths are not accessible or lend themselves only to the most dangerous and least successful forms of surgical attack

THE CONTROL AND TREATMENT OF CANCER

If a growth is accessible and local, no other method than that of operation should be considered The difficulty is to discover whether the disease at the time the removal of the growth is contemplated remains localised, or whether it has already extended to the primary glands, or perhaps has even spread beyond them. Nothing could more clearly show the advantages of early operation than the statistics collected from the Leeds cases by Miss Gretta Wardle, under the auspices of the Leeds Cancer Committee, and published by the Ministry of Health.

The report deals with 357 cases in which the tumour was submitted to microscopic examination Dr Janet Lane Claypon classified them on the following basis (Class I Cases in which, so far as could be ascertained, the growth was entirely confined to the breast, the axillary glands not being involved Class II Cases in which the axillary glands were already invaded, but in which there was no evidence of involvement of any other neighbouring or distant organ or tissue Class III Cases in which either the adjacent or distant organs or tissues are involved—e g, the pectoral muscles, the skin when ulcerated, the cervical glands, the opposite breast, &c

Excluding cases unclassified on account of insufficient clinical and pathological data, the following are the results of operation after three, five, and ten years respectively —

	Percentage alive at—		
	3 years	5 years	10 years
Class I	89 6	85 1	71 4
,, II	36 3	18 5	5·2
,, III	28 0	13 5	5 6

These and other figures given in the report prove that cancer can be completely eradicated if the local growth is early and widely extirpated They show that the degree of success depends upon the stage of the disease attacked by the operation If, however, the growth is inaccessible, or become disseminated, then no operation can eradicate it, and recourse must be had to other methods Of these, by far the most valuable is the therapy of the deep X rays From their skilled application the most remarkable results are occasionally observed The retrogression of the disease, or even its disappearance for two or three years, do not justify the use of the word "cure" Though we have seen the most striking results—results which five years ago could not have been believed possible—we have never seen a patient "cured" by this treatment The best testimony to the truth of this view of X ray work is shown by the refusal or reluctance of the skilful radiologist to undertake treatment in any case in which surgical measures are possible This means that only the cases in which surgery can do nothing are undertaken by the radiologist, and yet it is in these very advanced and otherwise hopeless cases that results are obtained which show the efficacy of the method In certain cases radium has its uses, and very remarkable temporary results are obtained It is only, however in cases of rodent ulcer, and by no means always even in them, that permanent freedom from recurrence has been observed Of the lead treatment of Blair Bell we cannot speak with certainty We must remember that his only chance of success is with the case in which everyone else has failed, with this category of the outcast he has certainly done better than any man

CONCLUSION

The points upon which we should at this moment concentrate our attention in our fight against cancer are, therefore, two —

1 To make the very utmost of our present methods which are applicable to all cases of accessible growths

2 To undertake research so that we may discover the cause or causes of cancer, and so be enabled to do something for the prevention of the disease or for its cure by methods other than those of surgery

We do not make the most of our present methods, and we are not likely to make the most until the public is instructed in some of the matters essential for them to know if they are to seek help in that stage of the disease which is capable of cure There are many medical men who regard with dismay or disapproval the suggestion that the public should be educated in matters concerning cancer It is said we shall "frighten them to death" I prefer to think that we are frightening them to life The problem of cancer is so simple and straightforward that any intelligent person may understand it, and by understanding it, learn to dread not cancer but neglect of cancer

As for research it is, perhaps, hardly too much to say that the conquest of cancer is a question of mon y Research, ceaseless research by trained skilful workers, research of the widest kind into all aspects and relationships of the disease, will surely capture the most elusive secret of its causation

Dr W E Gye, whose authority is indisputable, has said that " during the past 25 years—that is to say, during the period of experimental research into this disease—there has been greater progress in the study of cancer than in the study of any other single serious malady that attacks human beings " We hope that research may discover the cause or causes of cancer, and enable us, perhaps, even to prevent it or to rescue its victims by some other method than that of operation. The enemy grows yearly in strength, and though we are defeating him in some of his strongholds he is gaining on us elsewhere The time has come for a great national uprising against him

An Address
ON
ABORTION.

Delivered at a Joint Meeting of the Section of Obstetrics of the Royal Society of Medicine and the Medico-Legal Society on Jan 21st

By JOHN S FAIRBAIRN, B M OXF,
F R C P LOND, F R C S ENG,
OBSTETRIC PHYSICIAN TO ST THOMAS'S HOSPITAL, LONDON

I WILL endeavour first to give an idea of the medical indications for the induction of abortion and then to state the problems involved in it

MEDICAL INDICATIONS

The reproductive function is one that, like severe physical exertion, tests all the bodily functions, and under it some women will break down, even if previously perfectly sound The chemical processes are liable to become disordered and poisonous bodies may be formed causing damage to the liver and kidneys, the organs especially concerned in the modification and excretion of waste products The proportion of women who show signs of such failure is small, a fraction of 1 per cent Should it (toxæmia of pregnancy) occur, however, and not yield to treatment, the risks to the mother are great; in the worst cases, happily rare, she may go into convulsions and coma (eclampsia) or suffer from dropsy or uncontrollable vomiting, but the commoner danger is that of chronic kidney disease (Bright's) These cases are easily picked out by analysis of the urine and other tests, and when they do not yield to treatment are universally accepted as justifying the termination of the pregnancy, the more so because in kidney disease death of the fœtus in the womb occurs in nearly half the cases

The cases in which pregnancy occurs in a woman with some chronic disease that may be aggravated by the pregnancy form another group, in which, however, the results to be obtained from terminating the pregnancy are less certain and more open to difference of opinion In some diseases, such as chronic kidney disease and diabetes, there will be general agreement that pregnancy should be ended, but in regard to tuberculosis, heart disease, grave malnutrition, nervous and mental states there is room for wide variation in practice The effect of the pregnancy is speculative, but many accept without question the ill-effect that they think may arise and end the pregnancy forthwith Others advocate induction of abortion only when there is definite evidence of the disease being aggravated In heart disease, for instance, my own experience is that if the woman does not improve by rest in bed and medical treatment neither will she improve by ending the pregnancy, and sometimes the operation acts as the finishing touch. The case of a woman who has suffered from insanity in a previous pregnancy is an especially difficult problem Should the next pregnancy be ended for fear of a return of the mental disorder that may or may not recur ? The usual rule is that if the second pregnancy has followed soon after the one in which the trouble arose it should be terminated, also in any case in which insanity has occurred in more than one previous pregnancy On the other hand, if there has been some complication not likely to recur, such as excessive bleeding or septic infection which was clearly the provoking cause of the mental disorder, it is usual to allow the pregnancy to continue and trust to general medical treatment There is, however, in all serious disease of the mother something to be said for relieving her of the physical and mental strain of bearing and rearing a child, even if statistics show little gain from it

Laymen will readily appreciate, however, the difficulty of the medical practitioner who is faced with the case of a woman suffering from a serious medical condition or who has had previous mental disorder and is pregnant The husband and relatives look on the pregnancy as an aggravating factor in her condition and press for its removal The doctor may know that its effect is of no moment, but he will never convince his patients, and the pressure on him becomes too strong to resist Or again he may recognise that a tuberculous pregnant woman will do best in a sanatorium, but he cannot find accommodation for her or she may refuse to leave home, and he adopts the easy alternative of putting an end to her pregnancy.

The commonest reason, in hospital at any rate, for resort to this operation are the cases in which abortion has already begun, either spontaneously or from some accidental cause, or provoked by the taking of drugs, and the woman is ill from the hæmorrhage or infection of the damaged pregnancy or portions of it left in the womb There are also less common cases in which the pregnancy is found to be diseased and incapable of further development and a possible source of danger to the mother, generally accompanied by bleeding or enormous excess of the waters In these cases the only room for differences of opinion would be as to when the evidence was sufficient to indicate that the pregnancy was too damaged to continue or that it formed a definite risk to the mother These points granted there would be general agreement as to the need for its termination The cases in which labour is brought on prematurely when the mother is too small to allow of the passage of a full-time child fall into a different category, because the operation is done with the object of saving and not destroying the life of the fœtus

THE PROBLEM STATED

The original principle that guided the profession was that the procuring of abortion was lawful only if the woman's life was in danger if the pregnancy continued, but that principle was rightly extended to include also serious or permanent damage to her health For example, it has always been recognised that the serious eye changes that may occur with the kidney lesions in pregnancy were in themselves a definite reason for bringing the pregnancy to an end Rapid amelioration of the sight resulted. If the pregnancy continued permanent impairment and sometimes total loss of vision resulted We have only to think what blindness of the mother means to her family to realise how clearly interference is justified

Before, however, damage to her health can be predicted the woman must be kept under observation and treatment for such time as would suffice to show that progressive deterioration of her health left no alternative to the induction of abortion The consequences to the patient can be estimated only by taking into account what has happened in her previous pregnancies—if she has had any—how she is affected by the pregnancy in question, how far the effects have yielded to or resisted treatment, and by experience in, and knowledge of, similar conditions in other patients. The decision must be made largely on probabilities and there is room for much difference of opinion Hence the need for consultation.

As will be seen from reports [1] of the discussion at the last annual meeting of the British Medical Association, the principle of danger to life and health of the mother has also been jettisoned, and many in the profession go so far as to act on the supposition that it is not unlawful to take into consideration other than purely medical factors and to allow social, economic, eugenic, and other reasons to weigh in justifying the induction of abortion Such, for instance, as that the patient refuses to leave home or to try the effect of some special line of treatment, a girl's own story that she has been drugged or raped (especially if by a black man), that one or other parent is an epileptic or of feeble mentality, and so on

The effect of the spread of these laxer views is cumulative and produces a vicious circle, for once the public learns that abortion can be procured "respectably" under the guise of medical indications, every woman fails to see why her medical attendant should hesitate in her case, which, she is convinced, must provide an adequate excuse

Causes of Lower Ethical Standard

There are many causes contributing to this lowering of the professional standard of responsibility towards the procuring of abortion Resort to operative procedures is much more common owing to their greater safety and ever-increasing possibilities of speedy relief, and all operations are undertaken with much less consideration than was formerly the case The attitude of the general public must affect the medical profession which is part of the public and serves it The ethical standard of the public, never a high one, became lower during the war, though never falling as low in this country as in some mid-European countries that were especially affected by economic stress—e g, Austria and Russia The birth control propaganda that has followed the war probably arises from the same causes and likewise tends to produce a slackening of moral standards on the destruction of a pregnancy The factor, however, to which I would ascribe the chief influence is that of changing social conditions and their effect on the women of the day Our womenkind have secured wider interests and much greater opportunities than were open to their Victorian predecessors and crave for much more than a family life For these gains they have paid in a greater tendency to nervous exhaustion They may have wider fields open to them than their grandmothers had and be better equipped to till them, but their capacity to endure strain has not increased proportionately, and so far as the reproduction of the species is concerned they are inferior They would die—or they would have us believe so—if they produced families half the size of their grandmothers, and they call for much more in the way of artificial aid in childbirth

To illustrate this aspect of the problem as it confronts the medical profession to-day let me draw an imaginary picture Imagine a wife of the highly-strung over-sensitive type with two or three children and full of anxieties regarding their education and upbringing She has been trained to a professional or commercial life and still adds to the family budget by her earnings Finding herself pregnant again she is in the depths of despair She has made very heavy weather of her previous pregnancies and labours, her husband dreads again living through the months of the trials he has experienced before, and the two appeal to their family doctor to find some excuse by which her pregnancy and the consequent depression and nervous strain that fall on the whole family may be got rid of An actual case of this kind was reported in the B M A discussion which I would like to consider in some detail as a sample It has a topical touch about it, too, for it concerns a learned counsel and his wife—the latter of "a sensitive artistic temperament" A third pregnancy had followed after rather a short interval and Mr and Mrs K C had decided that her health might be affected, and the following casuistic argument is found seriously set out in print "Both she and her husband took the view that, the prospective baby being theirs, it was their own affair whether they allowed their work to be completed or not." If the baby had not been "prospective"—as would eventually have been the case had the processes of nature not been interfered with—would these two worthies have taken the view that it was still their own affair whether they allowed its natural development to continue or not? After consultation with a second obstetrician abortion was induced because "rapidly recurring pregnancies often affected the mother's health very unfavourably" The sequel, however, best shows up the illogical character of the whole proceeding Within six months she was pregnant again and returned to her doctor for relief, but the pernicious effect of rapidly recurring pregnancies apparently no longer sufficed However, though "flatly refused" by the original consultants, the legal couple proceeded to a medical colleague "whom they found more pliable." As a speaker in the B M A discussion remarked, "A patient's own or her husband's reasons for getting rid of an ovum should never be accepted, as there will generally be some selfish or sinister reason undisclosed" In this case the obstetricians fell easy victims to the specious argument of the learned counsel and no attempt was made either to test by observation what basis there was for his fears for his wife's health or to attempt any other form of treatment than the one desired I would like to put two questions about this case Had the lady and her husband come to a hospital, would the same treatment have been adopted? Had she been unmarried and unwilling to go through her pregnancy because she was apprehensive of its causing irreparable damage to her social health and position, would the treatment have been the same?

A Criterion Proposed

It is the frequency of cases of this kind that has served to weaken the former reluctance of the profession to resort to the procuring of abortion save for grave danger to the mother Such cases have enough in common with those fashionable explanations for aberrations of conduct—loss of memory, temporary irresponsibility, kleptomania, impulsive action, and others of the like, as announced in the press or pleaded in court, that they should arouse some fellow feeling for their medical brethren in the breasts of the legal profession The most useful result that might come from this combined discussion would be the formulation of some guiding principles that might help the medical profession to steer a safe middle course between allowing their patients to suffer serious injury to their health and overstepping the Common Law of the Realm

For my own part I would advocate that none other than purely medical considerations be allowed to weigh, and here I at once cross swords with my colleague who opened the *B M A* discussion with the following hopelessly inverted *statement* of the position I am sure this meeting will not be bluffed into studying the problem upside down as he tried to present it He says: "*It* is an ethical question of great interest to what *extent* we, as doctors, have the right to insist that a woman shall pass through an ordeal which she is unwilling to face, even if we do not think that she will sustain any permanent injury from so doing" The "right to insist" forsooth—it is not the right *to insist*; it is, have we the right to interfere with a *normal* pregnancy?

---

[1] The Lancet, 1926, ii, 378, Brit Med Jour, 1926, ii, 237

Once other than purely medical factors are allowed to count no line can be drawn between criminal and therapeutic abortion As a profession we are not trained in sifting evidence, nor can we question our patient's own story as to how she came by her pregnancy In the next place, granting that anxiety and mental distress over an undesired pregnancy may cause disability and "nervous breakdown," can any line be laid down for these difficult and border-line cases? As one of those taking part in the B M A discussion said in regard to the psychological problems · "Surely nothing could be worse than the mental torture of illegitimate or illicit pregnancy?" Are we, then, justified in terminating these? If mental distress over the occurrence of a pregnancy is admitted as an indication for abortion, how are limits to be set to the operation? And surely the single girl should have the preference over the married woman with children, although it is the former cases that most often lead to hesitation on the part of the medical attendant for the reason that they are more liable to lead to suspicion as to motive

I would suggest to my obstetric colleagues that we think this matter out in terms of hospital rather than of private practice, for the cases of the kind now under consideration are relatively very rare in hospital The reasons for the difference between private and hospital practice are not far to seek The private practitioner is in much closer personal relationship with his patients, by whom he is retained as adviser, and they, in paying the piper, demand some say in calling the tune He is thus much more influenced by his patients and his patients' relatives, and his judgment is diverted in the direction of their wishes, and he is on the whole more affected by the attitude of the general public than the consultant in hospital practice

In hospital other than purely medical factors do not weigh and the patient is kept under observation and treatment, and only if her condition is too serious to brook delay, or if other measures of relief have clearly failed, is abortion resorted to Medical treatment has also greatly advanced in the last 25 years Hence the guiding principle I would urge for these nervous or psychopathic or other border-line cases is the hospital method of observation till the symptoms are proved to be genuine and unrelieved by treatment and only as the last resource should the pregnancy be destroyed The case already quoted affords a good example of failure to adapt hospital methods to private practice

There is another point calling for the opinion of our legal brethren that is well set out in Döderlein's "Handbuch" (vol iii, p 18) in which three paragraphs from the German Penal Code are quoted setting out the number of years' imprisonment for the various persons who may be concerned in the destruction of a pregnancy and without exception whatsoever for persons or reasons A later paragraph from the Code is then quoted in which even longer years of "strafing" in prison are laid down for one convicted of causing the death of a fellow creature from negligence, and the writer goes on to ask what is the doctor to do? He may be called on to answer in the courts a charge of abortion procured on purely medical grounds or a charge of causing the death of a mother by his neglect to terminate the pregnancy which led to her decease. I would like to know how this dilemma, as made in Germany, might hold good in this country

ETHICS OF ABORTION.

It is obvious why all civilised nations protect themselves against abortion-mongering, for it is but infanticide anticipated by a few months The destruction of a pregnancy—at whatever stage it is done—is the destruction of life and the killing of a potential citizen, though it is too much to expect the populace to think that the non-sentient embryo is of much account Wherever and whenever there is little regard for human life the destruction of a pregnancy will be of no moment. The detection and legal proof of abortion-mongering is always a difficult matter and the vast majority of cases go undiscovered The degree to which the practice exists in any community will vary chiefly with the civilisation and moral standard of its people as a whole and on their respect for the laws under which they live, so that in some nations the laws against abortion-mongering may be so far disregarded as to be in practice non-existent. So far as I know the Soviet Republic of Russia is the only State in which abortion is actually legalised [2] If the lax views of many of the profession become general the Bolshevist system of unrestricted abortion-mongering will become a vested interest of those on the Medical Register, who will become merely the instruments of those patients who hire them for the purpose

To avoid this degradation the following guiding rules are brought forward as a basis for discussion.

1 Medical indications alone should be considered.
2 Medical indications should be defined as those clearly involving danger to the life of health of the mother or damage to the pregnancy sufficient to interfere with its future development, and the onus of proof should rest on the practitioners concerned.
3 In doubtful or border-line cases observation of the patient away from home and failure of other methods of treatment should have proved that abortion is the only resource.

ETHICAL, LEGAL, AND MEDICAL ASPECTS OF ABORTION *

BY LORD RIDDELL

As an observer I have noticed the simultaneous development of two conflicting lines of thought and practice amongst obstetricians. On the one hand an increased regard for the safety of the child as compared with that of the mother, and on the other an increased tendency in some quarters to procure abortions Obstetrics being the most important and widespread branch of medicine, affecting as it does every member of the community, the opinions and practices of high priests who set the standards and control the education of students and midwives are subjects of national importance. In my capacity of an observer, perhaps I may be permitted to state what I regard as the causes of these two trends of obstetric opinion and practice.

TWO TRENDS OF OPINION.

The increased concern for the safety of the child, as compared with that of the mother, seems to be due to three reasons First, the improvement in the art of midwifery, which has led the practitioner in abnormal cases to adopt various gadgets (I use the word in no invidious sense) with the object of producing a live child The development of most arts is characterised by increased finesse. Midwifery is no exception Second, the natural revolt of doctors, practising in a humanitarian age, against the destruction of fœtal life, particularly by barbarous methods such as craniotomy; and third, the direct and indirect propaganda of the Roman Catholic Church which teaches that abortion is not permissible and that the fœtus must not intentionally be destroyed to save the mother's life or to protect her health.

The increased tendency to procure abortions seems to be due, first, to a growing desire on the part of medical men to please their patients—the pontifical doctor is becoming a thing of the past; second, to the decrease of religious inhibitions; and third, to the safety and simplicity of modern methods

---

[2] Those interested in the conditions in Russia may be referred to the Medical Review of Soviet Russia (Brit Med. Jour, 1926, ii 802) by Dr H Gantt, American Relief Administration

* This paper followed Dr Fairbairn's at the meeting on Jan 21st.

These two sets of ideas act and react on each other and produce what may be termed “the modern midwifery atmosphere” When the first set is uppermost it may lead to undue suffering and risk for the mother When the second prevails it may cause the practitioner to destroy fœtal life unnecessarily and also to commit illegal acts

Before discussing definite problems that have to be faced in practice, it is necessary to consider the legal position, often misunderstood

THE LAW OF ABORTION

The law regarding abortion is comprised in the “Offences against the Person Act, 1861,” which provides that whosoever with intent to procure the miscarriage of any woman shall unlawfully administer to her any poison or other noxious thing or shall unlawfully use any instrument or other means whatsoever with the like intent shall be guilty of felony “Miscarriage” is a comprehensive term which includes both abortion and premature birth in the sense in which these words are understood by the medical profession, abortion being the expulsion of the fœtus during the first 28 weeks and premature birth expulsion after that period Miscarriage also comprises the destruction of the child during labour The term “unlawfully” is not defined, but obviously denotes a wrongful act, done intentionally without just cause or excuse. An adequate medical or surgical reason is the only just cause or excuse recognised by law for procuring a miscarriage The legal rule may be stated thus —

> It is contrary to law to procure, or attempt to procure, a miscarriage except with the object of saving the mother's life or avoiding serious injury to her health The essence of the offence is a guilty intent An honest effort to save the life or health of the mother is not illegal, although the practitioner may commit an error of judgment in performing an operation subsequently regarded by other practitioners as unnecessary He will not be liable to conviction if he honestly believes that what he does is required to save the mother's life or health If the mother dies in consequence of an illegal abortion, the person performing it may be liable for murder or manslaughter, but these offences cannot be committed in respect of a child in its mother's womb, as the child is not in *rerum natura* If, however, the child is born alive and subsequently dies, owing to injuries received *en ventre sa mere*, the offender may be convicted of murder or manslaughter (See cases quoted in “Russell on Crimes” Eighth edition)

Taylor's “Medical Jurisprudence” (seventh edition) states that in law “there is no such thing as justifiable abortion,” and that “the only reasons that can be thought of by an honourable man as justifying the induction of labour are · (1) to save the life of the mother, (2) to save the life of the child” This statement is open to serious criticism. Obviously the authors have overlooked or misinterpreted the word “unlawfully” in the Act of 1861. Furthermore, there is no doubt that a miscarriage may be lawfully procured not only to save the mother's life, but to avoid serious injury to her health The law is more accurately set forth in “Russell on Crimes,” which describes as lawful “acts done in the course of proper treatment and in the interest of the life or health of the mother” As to Taylor's reference to the life of the child, the statute deals only with measures to destroy the fœtus, and has no application to bona fide attempts to produce a live child or to preserve its health Furthermore, the Act does not relate to the removal of a dead fœtus

THE WELFARE OF THE PATIENT.

So far as I am aware, there are no legal decisions as to the pathological conditions justifying abortion This is not surprising I know of no case in which a medical man has been prosecuted for an error of judgment in procuring a miscarriage “Midwifery by Ten Teachers”—one of the latest text-books—says that “operations of this kind are confined to cases in which the life of the mother will be endangered or her health permanently damaged by the continuation of the pregnancy” But with all due respect I think the word “permanently” inaccurate. Induction is not only justifiable, but a duty, when the prognosis indicates grave danger to the mother's health, whether the results are likely to be permanent or not. The danger must, however, be serious Induction is not justified for the purpose of avoiding minor risks of pregnancy, such as the use of forceps or perineal tears A woman who becomes pregnant must be prepared to undergo the ordinary discomforts of pregnancy and to take the ordinary risks Therefore the practitioner must not be influenced by the adjurations of the patient or her relations to relieve her of these Nor must he be influenced by economic considerations or by his sympathy for a woman who finds herself in a distressing situation, involving perhaps social ruin. In short the medical man must confine himself to the medical and surgical aspects of the case The statement in “Midwifery” that “it is the practitioner's duty to do all in his power to counteract the modern tendency to curtail families for the sake of the State as well as for the sake of the woman's bodily and mental health” is also open to question. I respectfully suggest that the doctor's sole duty is to consider the welfare of his patient In deciding on the necessity for abortion he should not be influenced by a predilection “in the interests of the State” either for large or small families

CONDITIONS WHICH JUSTIFY ABORTION

The standard text-books on obstetrics indicate certain conditions that may admittedly justify abortion Some are caused by diseases peculiar to pregnancy and others by diseases apart from pregnancy but aggravated by it Even a layman can understand that each case must be judged on its merits The practitioner must exercise his discretion, remembering that in the absence of just cause the procuring of a miscarriage is a criminal offence But he must remember also that the mother's life must never be sacrificed to her unborn child, even if she is suffering from an incurable disease, such as T B in an advanced stage On the other hand, the possibility of diseased offspring is no indication for abortion The practitioner is not entitled to engage in eugenic excursions of this sort, and it must be remembered that unhealthy parents occasionally have healthy children It should also be remembered that a woman is under no obligation to submit to Cæsarean section as an alternative to abortion Happily the necessity for these measures is steadily diminishing owing to improved methods in the treatment of disease and to improved obstetrics which lessen the strain on the mother during pregnancy and labour It is apparent that even the conditions described by the text-book writers must provide ample scope in many cases for the compliant practitioner and ample room for honest doubt on the part of the scrupulous one There are, however, cases of other classes that present even more difficult problems These are said to be increasing in number owing to the growing disinclination on the part of many women to submit to the normal discomforts of an unwelcome pregnancy

It may, however, be pointed out that this is no new phenomenon Juvenal (circa 60–140) has some well-known and emphatic lines on the subject “These, however (the poorer-class women), do undergo the risk of childbirth and bear all the fatigues of a nurse, but rarely does a woman in labour lie on a gilded bed, so powerful are the arts and drugs employed by such a one”

And in 1868, an American, Dr Storer, wrote a book “Criminal Abortion” in which he deplored “its awful extent” amongst American women who did not wish to be inconvenienced by repeated pregnancies We are too prone to pay undue attention to the abnormal The truth is that the mass of women are taking a more intelligent interest in the production of healthy children than at any previous period At a large child-welfare clinic with which I am connected, the mothers—all wives of working men—write yearly essays on the management of pregnancy that would do credit to doctors or midwives But let us take a few typical cases of a kind calculated to cause the conscientious practitioner serious anxiety and to afford the compliant ample scope

1 Case of Mrs Smith, aged 26 Fashionable wife of a well-to-do man. Married two years, two children Four months after birth of second child again becomes pregnant Much distressed Nervous, irritable, and out of control Says she vomits all she takes, and is sinking from constant sickness Darkly hints at suicide Begs medical adviser to terminate pregnancy

2 Case of Mrs Brown, aged 40 Wife of working man earning forty shillings per week Married 16 years Lives in two rooms Eight children Again pregnant A delicate highly strung woman, much run down by repeated pregnancies and hard work Loses appetite Loses weight Sleeps badly Suffers from severe vomiting Is in a most depressed condition. Prognosis doubtful Implores doctor to terminate pregnancy

3 Case of Miss Jones, aged 20 A cultured girl who has got into trouble Attempts suicide and presents unmistakable symptoms of mental collapse

4 Case of Miss Robinson, aged 30 A cultured woman who becomes pregnant owing to assault by a tramp Mental condition serious Threatens suicide unless pregnancy terminated

THE PRACTITIONER'S POSITION

What should the practitioner do under such circumstances? We know, of course, that he should invariably get the benefit of a second opinion, and we know that in modern practice it is usual to secure such an opinion from a specialist in the disease affecting the pregnancy It is for the specialist to say whether the woman can safely be allowed to go to full time Consequently in the four typical cases quoted, it would seem to be the duty of the doctor to call in a general physician or a mental specialist as may be most appropriate If he advises in writing that the continuation of the pregnancy is likely to kill the woman, ruin her health, or drive her into a mental home, then in my opinion, *quantum valeat,* as the lawyers say, the procuring of a miscarriage is not only justifiable but a duty Cases in which the patient misrepresents or exaggerates her condition with the object of persuading the doctor to terminate the pregnancy are not uncommon Therefore extreme care is necessary when making the diagnosis

It would be futile to disregard the fact that some practitioners are ready to seize on any medical or surgical reason to justify an abortion when desired by the patient to avoid an unwanted child It is useless to discuss such conduct The offence cannot readily be detected in the case of a married woman attended by two medical men Nevertheless it is a risky game When required to deal with a pregnant unmarried woman, the practitioner is faced with problems of exceptional difficulty and danger If he procures an abortion his motives are open to question, and if he fails to do what is necessary to preserve the life or health of his patient he is liable to grave moral condemnation and may possibly incur serious legal consequences When faced with such a problem, the practitioner should always remember that secrecy is the badge of fraud If he acts openly, and if he is supported by another sound opinion, he has little to fear if his motives are right It is not a crime for an unmarried woman to become pregnant, and her medical adviser has no right to condemn her to death or to serious morbidity because she happens to be unmarried

THE ETHICAL ASPECT

As to the ethical side of medical abortion, every one must obey the law, but the practitioner is under no compulsion to do what the law permits He may say to the patient, "I am of opinion that an abortion is necessary and therefore legally justifiable but my conscience will not allow me to procure it If you insist, you must go elsewhere" But in giving effect to ethical convictions the practitioner must not offer up a vicarious sacrifice To speak more plainly, the patient must not be prejudiced by her medical adviser's conscientious scruples Both law and ethics demand that her condition should be explained and that she should know that she is being attended by a doctor who has convictions which she may or may not share

In considering the ethical aspect of the question a brief history of the subject is necessary

GREEKS AND ROMANS

Although prior to the Christian era the practice of abortion was common among the Greeks and Romans, little is known as to their legal attitude in regard to it especially in the case of the Greeks. The Oath of Hippocrates (460–370 B C) forbids it, but the prohibition obviously relates to what we should call criminal abortion and not to abortion for medical purposes Also it is doubtful whether the Oath as we know it was prepared by Hippocrates. Additions may have been made by his disciples at a later date It is curious that the Oath is the only evidence that abortion was regarded with disfavour by the Greeks Certain Greek philosophers, notably Plato (427–347 B C) and Aristotle (384–322 B C) expressed themselves decidedly in favour of the practice Plato (Republic V, 461 C) was ready to allow those who had passed the limits of age prescribed for procreative purposes (20–40 years for the woman, 25–55 for the man) to practise promiscuous intercourse but only on condition that such couples should have no children "We accompany this permission with strict orders to prevent any embryo which may come into being from seeing the light" (Trans Jowett) Aristotle's opinion (Politics VII, 16) may be compared to that of modern advocates of birth control "When couples have children in excess and there is an aversion to exposure of offspring" (to destroy them), "let abortion be procured before life and sense have begun" (Trans. Jowett) Indeed, as Lecky says in his "European Morals," "the practice of abortion was one to which few persons in antiquity attached any deep feeling of condemnation" When specific acts of abortion were condemned, this was not on moral grounds, but because the rights of husbands had been infringed, or the devolution of property interfered with Cicero (106–43 B C) relates a case in which expectant heirs bribed a pregnant woman to procure an abortion and thus defeat the prior rights of her coming child She was sentenced to death (Pro. Cluentio XI) Havelock Ellis says ("Studies in the Psychology of Sex") that in accordance with the patriarchal basis of early Roman institutions it was the father and not the mother who had the right to decide on abortion, but I have not been able to verify this

The comparative indifference with which abortion was regarded by the Greeks and Romans is explained by the view generally held that the fœtus was not a human being or animal but *pars viscerum matris*. There is no trace of any Roman penal law against the practice until the time of Ulpian in the early part of the third century, when abortion was made a crime, but the Stoic Musonius, writing in the first century, remarked that "the legislators have forbidden women to procure abortion and inflict penalties upon offenders" Galen, writing in the second century, says much the same The Justinian Codex promulgated in the sixth century confirmed the laws of the Ulpian period but discriminated between abortion before and after 40 days in the case of a male and 80 in that of a female, thus following the Aristotelian idea, of which more hereafter How the practitioners divined the sex when considering whether to operate is not revealed Hippocrates had committed himself to the statement that boys quicken a month earlier than girls ("On the Nature of the Child"). The Roman Codex did not recognise the unborn child as a human being, and consequently abortion was not equivalent to homicide These laws may have been due to the enormous growth of the practice under the Empire, as morals became increasingly corrupt, or to the spread of the Christian religion. The Church early in its history set its face against abortion This was due partly to a revolt against the doctrines of the Aristotelian school who taught that there was. (1) a vegetable soul which came into being at conception; (2) an animal soul which developed a few days later; and (3) a rational soul that came into being after 40 days in the case of a male and 80 of a female The rational soul presented no difficulty. To the Church the rational and spiritual were a unity. Accordingly once rationality had attached to the corporeal child in the womb its destruction was logically murder The vegetable and animal stages, the *homo rationalis futurus* (the rational man to be) presented subtle intellectual problems.

The Mosaic Law

Abortion was not expressly prohibited by the Mosaic laws except that Exodus XXI., v. 22, inflicts penalties for injuring a pregnant woman in a brawl The New Testament is silent Therefore the question was whether abortion was contrary to the Sixth Commandment "Thou shalt not kill" The Christian Fathers faced the situation with characteristic resolution and more than characteristic precision Tertullian (155–222) voiced their views when he said, "Murder being once for all forbidden, we may not destroy even the fœtus in the womb To hinder a birth is merely a speedier homicide, nor does it matter whether you take away a life that is born or destroy one that is coming to birth" Gregory of Nyssa (fourth century) declared that "one identical life principle exists from conception to death" Similar pronouncements have been made from time to time by various ecclesiastical authorities These declarations involved strange results and made abortion a deadly sin The fœtus, being a human creature and therefore the inheritor of original sin, was certain of eternal damnation if it perished without baptism For this reason the Church still teaches that the life of the child must not be sacrificed for the mother's benefit Either she has been baptised or she has neglected her duty, whereas abortion would deprive the infant of baptismal rights In the Middle Ages little was heard of abortion, no doubt due to the universal authority of the Church In England in Anglo-Saxon times it seems to have been regarded as an ecclesiastical offence only (Stephen's "History of Criminal Law," Vol. I, p 54) Later it became a crime, see legal works of Fleta (circa 1290), Bracton (d 1268), and Coke (1552–1634) It should be noted that until the Act of 1861 already quoted, our law drew a distinction between a woman quick with child and one not quick. (Quickening is supposed to occur about the eighteenth week) This difference was embodied in the first statutes prohibiting abortion, 43 Geo III, ch 58 and 9 Geo IV, ch 31 If the offence was committed before the woman was quick, the penalty was imprisonment, transportation, or whipping If later, death From all this it appears that abortion, although tolerated before the Christian era, has long been regarded as an anti-social act, contrary to the welfare of the individual and the State This view is not based upon ecclesiastical doctrines as to viability that may or may not be justified by the facts or by the Scriptures When considering the ethics of medical abortion, it is important to note the distinction between an ethical rule made by mankind for their own protection and a natural law such as the Sixth Commandment.

The Biological View

The discussion is, however, complicated by the views of those who hold, for so-called biological reasons, that the life of the embryo is sacred even in its earliest stages The exponents of these opinions disclaim the influence of ecclesiastical dogma, but in effect agree with the Roman Catholic Church that one identical life principle exists from conception to death This doctrine involves subtle questions, which may be argued indefinitely both as to time and conclusions When does life begin? When does the child establish a separate entity apart from its mother? The Greeks and Romans revelled in such speculations Plutarch's "Morals" contains a quaint epitome of the opinions of several eminent persons on this abstruse subject, enlivened by the analogy of the unplucked apple Is it part of the tree or a separate entity? Xenophon and the Stoics regarded the fœtus as the fruit of the womb, the soul mind or intelligent principle being acquired at birth Aristotle's views have been described already It must be confessed that modern discoveries have not helped us to solve these metaphysical problems Logically the life of the microscopic embryo with its potentialities may be as sacred as that of the fully grown man, but human affairs are not governed by logic. Therefore we find that for nearly 3000 years the laity have not regarded the fœtus as a human being. This may not be logic but it is common sense Abortion is anti-social and illegal unless performed for an adequate medical reason But when such reason exists there is no ethical objection The doctrine that the mother is to be sacrificed or risked for the benefit of the unborn child is a resuscitated relic of the Dark Ages and biologically unsound On strictly ethical grounds, saving the mother's life or health is more laudable than the observance of theoretical ideas regarding the viability and rights of the fœtus As Dr Ballantyne says when summarising ideas, of which he disapproved, by the way ("Ante-Natal Pathology," p 459), "The mother's life has a value because she is what she is, while the fœtus only has a possible value on account of what it may become" Perhaps I may be permitted to add that consciousness may well be the test What evidence is there that the fœtus possesses this quality? The whole tendency of modern life is to abandon forms however venerable, and to concentrate on realities The ethical propriety of lawful abortion must be considered from that aspect As Aristotle says somewhere, scientific exactitude is impossible in reasoning upon particular ethical cases The circumstances of each case must be regarded Health is the purpose of medicine Therefore the doctor is justified, providing that he acts within the law, in doing what will be most conducive to the object of his calling

Essentially a Woman's Question

Hitherto abortion has been a question entirely in the hands of men—Christian ecclesiastics, lawyers, doctors, and politicians Yet it is mainly a woman's question In Germany it has been actively taken up by women (See Havelock Ellis's "Studies in the Psychology of Sex") German writers insist that the fœtus is not yet an independent human being and that every woman, by virtue of the right over her own body, is entitled to decide whether it shall become one I hope we shall all regard this as an anti-social proposition Nevertheless, it is certain that the practice of contraception would receive an enormous stimulus if the public thought that the lives and health of pregnant women were to be risked against their will and without their knowledge by reason of ethical objections to perform a legal operation

There are two further points that demand attention. The destruction of a full-grown child is a revolting affair, whereas the abortion of an early fœtus differs but little from the removal of a uterine tumour Even the Roman Catholic Church, in awarding its punishments, discriminates between early and late abortions See, for instance, Decretal of Pope Gregory IX (1244) defining abortion as homicide if the child had quickened, otherwise not Consequently it is the duty of the practitioner to perform the operation early if reasonably satisfied that it will be required sooner or later

Conclusion

Finally, how often should he procure abortion on the same woman? And how often should he perform a Cæsarean section? No doubt each case must be judged on its merits But this at least may be said. Procuring abortion involves serious and exceptional responsibilities which a patient is not entitled to thrust on her medical adviser Therefore she should be warned against future pregnancies and, in appropriate cases, sterilisation should be recommended Cæsarean section differs, of course, from abortion inasmuch as there is no express statutory prohibition, but if a Cæsarean section were performed unnecessarily and the patient died as a result the practitioner would be liable to conviction for manslaughter

Nature has ordained that children shall be produced in a certain fashion and abnormal methods are not justifiable to gratify whim or caprice Nor, it is submitted should the practitioner lend himself to a series of such operations If a woman cannot bear children in the usual way, she should be warned against further pregnancies that must result in abortion or in an operation attended by serious risk

NEW METHODS AND PRINCIPLES IN THE TREATMENT OF VARICOSE VEINS

BY A. L VISCHER, M D BÂLE, M R C S ENG

THE satisfactory results obtained by the injection of substances causing sclerosis in the treatment of varicose veins, which have been reported from many places, have rightly aroused interest.

In the present paper an endeavour will be made, in the light of personal experience to set forth some of the remedies which have been recommended, with their effects, and to add a few brief remarks about some new results of scientific research work, especially regarding the state of the circulation in the lower limbs, which are important for an appreciation of the new methods

All methods whose object is to destroy the varicose veins by injecting substances causing sclerosis date back to the Berne surgeon E Tavel, who, in 1904, recommended the injection of a 5 per cent solution of carbolic acid into the varicose veins This method however, was not adopted During the war German, French, and Austrian workers took up this treatment, using different substances. In most countries the treatment met with almost general disapproval because of the fear of embolism. The various scientists, however, went on with their experiments which had already given good results, and they now look back upon excellent results extending over several years On the basis of this experience the method can now be recommended without hesitation to the medical world

Various remedies are employed in this treatment J A Sicard and L Gaugier, Paris, use sodium salicylate in a 20 per cent., a 30 per cent, and a 40 per cent solution Linser in Germany uses a 20 per cent solution of sodium chloride, and lately G Nobl in Vienna has recommended grape-sugar in a 50 per cent solution having previously used a 1 per cent solution of sublimate in numerous cases

Apart from the authors mentioned many others have published their results; the above-named scientists deserve, however most consideration, as their experience extends over thousands of cases

Principles underlying the Treatment.

The action and principle are the same whichever substance is used When one of these remedies is injected into a varicose vein damage to the wall of the vein takes place A thrombus is formed on the damaged wall of the vein which is quickly organised An artificial thrombophlebitis is the result The artificially formed thrombi are remarkable for their great tenacity, for they do not become dislodged and no fragments are detached from them. The artificial abrasion of the intima and the resulting formation of thrombi can only take place in varicose veins The wall of a normal vein shows, indeed a great power of resistance against any damage by corrosive substances Salvarsan and sodium salicylate solutions of high concentration have been injected into the arm veins without the formation of any thrombi being observed The inner wall of the varicose veins as has been proved by numerous pathological-histological investigations, is almost always affected The wall is sometimes moderately hypertrophied, but generally it is atrophied, and in extreme cases the three coats have degenerated into a thin fibrous membrane

The extent of the artificial damage to the wall of the veins after an injection measures from 3–10 cm and depends on the strength of the injected substance and on the degree of dilution with blood in the injected vein. In rare cases the varicose veins of the whole leg are acted upon.

Unwarranted Fear of Embolism.

The suspicion attaching to this method and the unwillingness of many doctors to take it up originate in the fear of embolism The formation of a thrombus suggests at once the possibility of embolism All the above-named clinicians report, however, that they have never observed embolism occurring after the injection of substances causing sclerosis P. D. Linser cites more than 6000 cases in support of this assertion, Sicard and Gaugier several " thousand cases, and G. Nobl 2960 cases extending over eight years

The absence of any danger of the formation of emboli is not only empirically proved but can also be established by certain anatomical, histological, and physiological findings The damage to the inner wall of the vein is severe, and in consequence the adhesion of the thrombus formed is very close and firm The thrombus adheres, not only in one place, but in parts to a large proportion of the wall. The artificially formed thrombus has a tendency quickly to organise; in the wall of the vein a productive inflammation takes place, and strands of young vessels and connective tissue penetrate into the thrombus Later a transformation of the connective tissues occurs, the varicose veins which have been subjected to treatment close up, and ultimately become thick fibrous cords The adhesion of the artificial thrombus to its place of origin is further explained by the course and structure of the very sinuous, dilated, alternately expanded and constricted blood channel

The Circulation in Varicose Veins

To understand this new method a knowledge of the conditions of the circulation in the varicose veins is extremely important Trendelenburg s well-known experiment has taught us long ago that in varicose veins the valves no longer close the lumen The insufficiency of the valves is not the only sign of defects in the circulation. A. Jentzer's radiographic investigations with injections of a solution of bromide of strontium show that in varicose veins the blood does not flow towards the heart but towards the periphery G Magnus has studied the conditions of the circulation in varicose veins by introducing a hæmodrometer These experiments have proved that in the recumbent position of the patient the blood in the varicose saphenous vein flows towards the heart or, in many cases, is practically stationary. When in upright position, or even only on bending the leg 45 degrees the blood flows backwards towards the periphery, and the rapidity of the centrifugal stream is distinctly greater than that of the normal centripetal stream in the veins

This fact explains why, in people suffering from varicose veins, often complicated by thrombotic processes, pulmonary emboli are never observed when the patients move about or when they are doing heavy manual work, but are formed only when the body is in the horizontal position—e g, during intercurrent illnesses In fact, when a thrombus in a varicose vein becomes dislodged, it moves as a rule centrifugally into the fine branches of the saphenous vein and causes embolism of these vessels Magnus believes that the ulcers which suddenly appear and rapidly grow may arise in this way

It is an advantage in this method for the patient not to lie in bed after the injection, but to resume his ordinary employment

Technique

When making the injection care must be taken that the varicose veins are as free as possible from blood To give any results the solutions must act on the intima in high concentration, that is to say, practically undiluted It is therefore convenient to stretch the veins or to raise the lower limb during the injection

An objection to the treatment by injection must be mentioned; the solutions cause necrosis of all the tissues if they are not injected into the lumen of the vein The injections must be definitely intravenous, never perivenous or paravenous This demands a very exact and precise technique

Here is a brief account of the strength and doses of the solutions If a *1–2 per cent solution of perchloride of mercury* is used, an injection of from 1–3 c cm gives the desired result of irritation of the inner wall If *20 per cent, 30 per cent and 40 per cent solutions of salicylate of soda* are used, at one sitting 6 c cm of the 20 per cent solution, 4 c cm of the 30 per cent solution, or 2 c cm of the 40 per cent solution can be injected The *sodium chloride* is used in a 20 per cent solution and 5 c cm of this solution are injected In the case of *glucose*, Nobl recommends the injection of a 66 per cent solution, 5 c cm of this solution are sufficient to produce a satisfactory local effect The absolutely innocuous nature of the glucose makes it possible to treat several portions of the vein at one sitting

The use of fine needles with short bevelled points gives the best results, and it is advisable to use a new needle for each injection Before the injection the skin over the varicose vein is disinfected with tincture of iodine or alcohol It is of the greatest importance that the injection be strictly intravenous By drawing up blood into the syringe one has a test which can always be applied before or during the injection After the injection light pressure with a pad of cotton-wool is applied for two minutes to the skin where it has been pierced by the needle

General Remarks

Though this new treatment of varicose veins has given excellent results and is without danger—provided, of course, that it is carried out correctly—it must nevertheless be pointed out that a relapse is by no means always out of the question Either the artificially thrombosed veins again become permeable, or other veins degenerate into varicose ones This is, however, much more frequently observed after surgical treatment of varicose veins One need not hesitate to cure these recurrences by the injection method In such cases the patients will object less to a repetition of the injection than to a second surgical operation After a successful treatment by injection it is also important to improve the circulation in the lower limbs by systematic muscular exercise, and to avoid what is harmful, above all long-continued standing

INJECTION TREATMENT OF LOCALISED TUBERCULOUS LESIONS.

WITH SPECIAL REFERENCE TO CALOT'S PREPARATIONS

By ROBERT POLLOK, L R C S Edin,
L R F P S Glasg,
EX-SENIOR RESIDENT MEDICAL OFFICER, GLASGOW CORPORATION HOSPITAL AND SANATORIUM, ROBROYSTON

THERE is nothing new in the treatment of tuberculous lesions by injections, it has been strenuously advocated for many years by leading authorities on tuberculosis But in view of the many patients admitted to hospital who have already been operated on and who have profuse discharging sinuses, even amyloid disease, one feels justified in again calling attention to a line of treatment which to a large extent saves the patient from the dangers of these serious complications In the vast majority of tuberculous lesions operation is a mistake, the extent of which is not always realised by the surgeon, for he does not always see the end-result of his well-intended incision, or excision, as the case may be There is no short road to cure in tuberculosis of bones and joints

The most common complications of tuberculous disease of bones and joints are abscess and sinus formation In notes collected of 110 cold abscesses the relative frequency recorded was psoas, 28, gluteal (6 from spine, 6 from hip), 12, knee, 11; lumbar (7 from spine, 2 from sacro-iliac joint), 9; hip, 10; forearm, 6, dorsum of hand, 5, leg, 5; ribs, 5, thigh, 4, sternum, 4, elbow, 3, ankle, 2; retropharyngeal, 2, upper arm, 2, scalp, 1, foot, 1.

Technique of Aspiration for Abscess

Aspiration of a palpable psoas abscess, pointing either above or below Poupart's ligament, is a perfectly safe procedure provided that the puncture with sharp trocar in cannula is made, not through the skin directly over the abscess but in an oblique direction, so that the cannula will pass through a fair thickness of healthy tissue before entering the actual abscess cavity It is well before the puncture is made to slide the skin adjacent to that overlying the abscess, so that when the instrument is withdrawn and the parts return to the normal position the track is obliterated Both lumbar and gluteal abscesses should be aspirated laterally and not medially, so that when the patient is in dorsal decubitus, gravity will not assist the fluid contents to find their way along the needle track and create a sinus A psoas abscess is aspirated above Poupart's ligament at a point half inch above and to the outer side of anterior superior iliac spine. Aspiration should not be attempted unless there is definite evidence of fluctuation on deep palpation It is advisable, especially when aspirating on the left side, that the colon should be emptied beforehand by enema An abscess below Poupart's ligament pointing to the inner side of the thigh requires a little more care, the puncture should be made to the outer side of the femoral vessels, and the cannula passed behind them into the abscess cavity to the inner side of the thigh An anæsthetic is safer in a case of this kind, and should also always be given before attempting the aspiration of a retropharyngeal abscess In this case the needle is entered at the level of the second cervical vertebra at the posterior border of the sternomastoid It is passed straight in behind the carotid sheath till it strikes the transverse process of the second vertebra, and then passed forward over the anterior surface of the transverse process

Results of Trypsin Injection

The results of trypsin injection, which was tried in a small number of cases were not satisfactory Two patients with psoas and two with hip abscess were treated by aspiration and injection of 1 c cm trypsin In each instance the focal reaction proved too great to be controlled In one case of psoas abscess the abscess recurred so acutely after the third injection that it had to be incised, in the other three patients the abscesses broke through the skin Five cases with sinuses were also treated by injection of trypsin into the tissues surrounding the sinuses In one case only did improvement occur; thus, a knee lesion with several discharging sinuses, was given 6 injections of 1 c cm trypsin, and healing occurred four months later In the other four cases the sinus was connected with elbow, inguinal glands, hip and tibia, respectively, in no instance was any improvement recorded, indeed, in all it could be said that progress was definitely retarded

Treatment of Cold Abscess

The routine treatment for cold abscess subsequently adopted was aspiration accompanied by injection of Calot's modifying fluid

This consists of olive oil 70, ether 30, creosote 5, guaiacol 1, iodoform 10 parts The best olive oil is shaken up with absolute alcohol, 1 part of alcohol to 100 of olive oil, to remove certain impurities from the oil This mixture is then left in a filter funnel for about 12 hours, the alcohol floats to the surface, carrying the impurities with it, and the pure oil can be run off below *The oil is then sterilised by* boiling for 15 minutes The creosote, guaiacol, and iodoform are triturated in a sterilised mortar with a sterile pestle, and added to the oil when it has cooled below 60° C The ether is added when the mixture is cold The result is a clear light-brown fluid which should be kept in the dark in a sterile Erlenmeyer flask of about 250 c cm capacity capped with rubber It is not advisable to give more than 10 c cm as a dose once weekly, this can be repeated indefinitely as long as the abscess requires aspirating Smaller doses are given to children according to age

This modifying fluid was used frequently in Robroyston, both following the aspiration of cold abscesses and in the treatment of white swellings of joints It was found to be of distinct use in both conditions and there is reason to believe from the results obtained that cold abscesses dry up more quickly when this modifying fluid is injected after each aspiration than when the aspiration only is done Ninety-seven cold abscesses (including 20 psoas, 11 lumbar and gluteal, 12 hip and 9 knee abscesses) were treated by aspiration and injection. Of these, 66 healed, 26 (including 1 psoas, 5 lumbar and gluteal, 1 hip and 2 knee abscesses) broke down with sinus formation, 1 was improving when the child was removed by the parents, 1 abscess recurred four months later, and three cases developed nephritis which, however, could not be definitely attributed to the injections

Other cold abscesses, 18 in number (including 2 psoas, 3 lumbar and gluteal, and 2 knee abscesses) were treated by aspiration without injection Of these, 12 (including all the psoas, lumbar, gluteal and knee abscesses) broke down with sinus formation and 6 healed Treatment by aspiration is *comparatively* futile in the case of disease of elbow, ankle, and glands because of the rapid involvement of the skin Thus, of 4 abscesses at elbow-joint treated, 2 healed and 2 broke down, of 3 at ankle-joint, all broke down, of 15 gland abscesses treated, 13 broke down and 2 healed

Treatment of Sinuses

Sinus formation in disease of the spine, hip, and knee is a disaster of high import in the order given Nevertheless, although a serious problem it is not one incapable of *solution* Sinuses can be healed The material used almost exclusively was Calot's No 2 paste

It is composed of phenol camphor, 3 g, naphthol camphor, 3 g, guaiacol, 8 g, iodoform, 10 g, lanoline, 150 g, spermaceti, 100 g The lanoline and spermaceti are mixed and heated to boiling-point in any kind of vessel, preferably one of porcelain or earthenware The mixture is stirred continuously to prevent boiling over, and is then allowed to cool to 122° F, and the other ingredients which have been carefully triturated in a sterilised mortar are then added to it Phenol camphor is composed *of equal* parts of phenol and camphor, naphthol camphor of one part naphthol to two of camphor The paste, which must be kept from the light, is solid at ordinary temperatures and is of a fine yellow colour It is best kept sterile in sterilised glass jars with glass stoppers It liquefies at about 105°, and is solid at body temperature For use the jar is placed in hot water about 140° until the paste liquefies This generally takes about 20 minutes The ordinary all-glass 10 c cm urethral syringe is the most convenient to use for injecting sinuses One should be just as careful about asepsis as for an aspiration The jar should always be shaken and the liquid paste injected at a temperature of about 103°

If there are several sinuses these very often communicate, and when one sinus is being injected the paste appears at the orifices of others Wherever it appears it should be frozen hard with the ethyl chloride spray and a dressing held over the plugged sinus, so as to enable all the interstices to be further filled The nozzle of the syringe should be kept within the orifice until the paste has solidified Solidification may be assisted by spraying ethyl chloride around the sinus opening The injections are repeated every fourth day on ten occasions and at the end of that time treatment is stopped for a month If then the sinus remains unhealed, another course of injections should be given It is not advisable to give more than 20 c cm as a dose and it is exceedingly rare to find a sinus suitable for treatment that will hold more than 10 c cm Both lanoline and spermaceti are organic substances easily absorbed in the sinus cavity, and are thus less likely to interfere with drainage than mineral substances like paraffin The other ingredients act in very much the same way *as they do in the case of the abscess wall* They provoke a localised hyperæmia and reaction in the sinus wall, with possibly a slight increase of discharge for a day or two following the injection, and in the end promote the cicatrisation of the tuberculous granulation tissue lining the sinus.

Contra-indications

Calot mentions albuminuria and septic infection causing pyrexia as contra-indications to this form *of treatment* Seventeen patients with sinus formation complicated with albuminura were treated, in most of them the albumin did not amount to more than a trace Only two of these sinuses healed, one of which was from disease of ilium and the other had followed a ruptured psoas abscess The latter case had no albumin after healing; in the other it continued None of the other 15 cases showed any improvement; in fact, several have since died of amyloid disease It was noticed that post-operative sinuses were considerably more difficult to heal than sinuses occurring in the natural course of the disease, 10 only healing out of 27 This was probably due to the greater amount of dense scar tissue *present* in the wall of the former type of sinus rendering purification, revascularisation, and healing more difficult No case was treated by this method in which the degree of sepsis was at all marked—i e, cases with discharge at all profuse or with evening temperature approaching 100° Of 80 other cases, in which the sinuses had arisen without operation, 58 healed entirely on treatment and 22 remained unhealed Of the cases which did not heal, one, a psoas sinus, developed acute nephritis during his second course of injections and he eventually died, another patient with an ankle sinus developed a severe septic reaction, amounting almost to erysipelas, around the sinus and treatment had to be stopped; two cases were taken home by parents before treatment could be completed, and four cases developed acute dermatitis around the sinus and the injections were stopped in consequence There is a small proportion of patients whose skin becomes severely irritated by the paste, probably owing to an idiosyncrasy to iodoform.

Of the total 124 cases, the culture of secondary infecting organisms was attempted in 61 The most common micro-organism was *Staphylococcus albus*, alone or in combination with streptococcus or with a Gram + diphtheroid bacillus This last was grown in seven instances Coliform organisms were grown from sinuses on six occasions, being *Bacillus coli communis* in three of these The presence of streptococci proved an insurmountable barrier to success in treatment in most cases *Staphylococcus aureus* was an equally difficult invader to deal with In no case in which a coliform bacillus was present was healing obtained The sinuses most easily healed were those found sterile on culture or infected merely with *Staphylococcus albus*, alone or in combination with the diphtheroid bacillus

Treatment of Ulcers.

Tuberculous ulcers can be very successfully treated by means of an ointment containing the same ingredients as Calot's paste in the same strength If the cetaceum is omitted and double the quantity of lanoline used a very good ointment is obtained, which seems to provide the necessary stimulus to healing in shallow ulcers which it would be impossible to inject with the paste.

Treatment of Tuberculous Joints

In "Indispensable Orthopædics" Calot warmly advocates injection of his No 1 fluid into joints affected with tuberculous arthritis with the idea of causing sclerosis Two c cm or more of the fluid are injected into the joint by means of a Record syringe once weekly for ten weeks through suitable skin punctures A rest of a month is then given followed by another course of injections if necessary A number of tuberculous knees were treated by this method, but in eight only was treatment carried out long enough to give one a fairly accurate idea of its value. In one adult an abscess and sinus followed the fifth injection The sinus was successfully treated by means of injections of paste and excision was performed later with good result In two other adult cases abscess formation occurred during treatment and this complication is still being treated in one; in the other there has been no sign clinically of active disease during the last four months and the patient is now ambulant Other two adult cases both with extremely painful knees ankylosed in extension benefited considerably on treatment, and one left hospital five months after its completion wearing a celluloid splint over a firmly ankylosed and painless knee. The other showed signs of fresh activity of disease after having been ambulant for three months Excision had to be performed in this case also The remaining three cases treated were children with pulpy synovial swelling of the knee-joint, in only one of which was there any erosion of cartilage demonstrated on X ray examination All three cases did extremely well They each had only one course of injections. In all three swelling of the joint was found to have considerably diminished in size about two months after treatment had stopped In the two cases in which the synovial membrane alone was diseased, movement which had only been possible through a few degrees gradually increased in range until six months after treatment had ceased flexion and extension was possible through 90° In the third case firm ankylosis occurred in the position of extension All three cases were dismissed in celluloid splints clinically cured less than a year after treatment had been commenced The treatment might then be described as having been successful only in the early lesions of children Only five cases of tuberculous hip disease were treated by this method All five were children with hips still extremely painful on manipulation and showing no signs of progress after many months of extension in bed; in none was abscess or sinus present In one abscess formation occurred after the eighth injection; this complication was satisfactorily treated to a conclusion and there was latterly no pain on attempted manipulation of the joint In another child an abscess formed during the second course and here again pain was latterly absent The remaining three showed marked improvement on treatment, and two months after the second course of injections had ceased each had painless hip and had put on weight.

Treatment of Tuberculous Glands

Practically no success has been obtained in treating tuberculous glands by injections No matter how careful one's technique in aspirating, a gland abscess, once formed, almost invariably gives rise to a sinus. It has been found that those compounds specially recommended as causing liquefaction in caseated glands do not fulfil that expectation They cause considerable pain on injection and very often provoke a severe reaction in the shape of marked localised swelling and tenderness. The sulphoricinate of soda compound is particularly severe in this respect, the skin over the gland generally sloughs and leaves a nasty fungating ulcer Camphor naphthol in glycerine also provokes a severe reaction, although not nearly so severe as the one first mentioned It has never in our experience caused liquefaction in a gland mass, although it does cause pus already formed to become more liquid and easier to aspirate Six cases were tried with a compound termed ethyliodoricio-oleate made by Burroughs Wellcome and Co The enlarged gland masses were injected bi-weekly on ten occasions; although no severe reaction resulted, the treatment was found to be of little avail as far as the absorption of the tumour was concerned Probably it is better to try treatment by aspiration in the case of a gland abscess already formed, as even if it does break down on treatment, as it almost always does, the cosmetic result on healing is probably better than if one operated at that stage But in cases of ordinary enlarged tuberculous glands before the stage of abscess or sinus formation there is no doubt that operation combined with sanatorium treatment gives much the best result

In concluding this paper I should like to thank Dr G Watson, the superintendent, and Mr G Taylor, the visiting surgeon for liberty to make use of the material provided I should like also to thank Dr E McPhee, Dr G C Campbell, and Dr A H Bowman, former residents of the hospital, for permission to use their notes on cases under their charge for the purpose of this article.

Clinical and Laboratory Notes.

TWO CASES OF
STRICTURE OF THE JEJUNUM

By Alan C Perry, M S Lond, F R C S Eng,
ASSISTANT SURGEON TO THE LONDON HOSPITAL.

The following cases are considered to be of sufficient rarity to be placed on record

Syphilitic Stricture of Jejunum

J K, male, aged 58, was admitted with a history of seven months abdominal pain coming on two hours after meals The pain was colicky, appeared suddenly, and died away gradually, and was occasionally relieved by food. It might also persist for one or two days without relief, but on two occasions the patient was free for about a week The pain began in the left hypochondrium and then radiated round the lower abdomen to the right, finally spreading diffusely over the abdomen, it was accompanied by much rumbling of the intestines The patient had been doubled up occasionally and awakened at all times of the night

Vomiting occurred several times but it had little relation to the pain and was present with constipation, it often relieved the pain The vomit varied in amount and sometimes contained undigested food, there was never any hæmatemesis Constipation was prominent and was always associated with the pain, for two months it had alternated with slimy diarrhœa The constipated stools were described as being like nuts and the patient said that he had lately lost a considerable amount of flesh There was no melæna and no jaundice

On examination the abdomen was found to be distended especially in the flanks Visible peristalsis could not be discovered There was tenderness at a point in the left hypochondrium corresponding to the site of origin of the pain, and the rectum, which was empty, was dilated

Radiographic Examination.—An opaque enema was administered and the appearance was in favour of an annular obstruction of the ascending colon. An opaque meal was advised but the patient's condition made it impracticable. The constipation became worse and proved intractable to enemata. Distension increased and it was decided to explore the abdomen.

Operation.—The abdomen was opened by a right paramedian incision. The cæcum was collapsed and no abnormality was discovered in the large intestine. The small intestine was found to be enormously dilated in its upper part. The contracted portion was traced upwards and led to a ring-like stricture which was hard and had almost occluded the lumen of the gut. Above this the gut had a diameter of 2 inches, the wall was thick, œdematous, and somewhat congested. The neighbouring mesenteric glands were enlarged, and one of them was enucleated for microscopical examination. In view of the state of the intestine above the stricture it was decided not to perform lateral anastomosis, and the stricture was brought out in a loop. Jejunostomy was then done with a Paul's tube, and a spigot was passed through the mesentery.

After operation large quantities of feculent fluid drained from the tube, but the patient developed bronchopneumonia on the fourth day and died on the seventh.

Pathological Reports.—The excised gland was described as a "fibro-caseous and granulomatous lymphatic gland from mesentery, possibly Hodgkin, possibly syphilitic. No evidence of tuberculosis."

The post-mortem report described the condition as follows: "Almost healed ulcer encircling and causing great stenosis of lumen of intestine, 8½ feet below duodenojejunal flexure and 10½ feet above the cæcum. Thickening by tough pliable fibrous tissue of wall of intestine at site of ulcer. Great distension (9 cm. circumference) and muscular hypertrophy (0.3 cm. thick) and œdematous thickening of mucosa in jejunum above stricture. Severe mucous catarrh above stricture. Moderate distension without hypertrophy of small intestine below stricture. Collapse of large intestine. Paul's tube 6 cm. above stricture. Extensive fæcal staining of laparotomy wound in abdominal wall, none of peritoneum. Severe general exudate of fibrin and pus throughout abdomen. No other ulcers or scars in intestine. Lymphatic gland in middle tier of mesentery entirely replaced by grey dense fibrosis and one rubbery area of necrosis. No abnormality save for slight chronic inflammatory swelling in other mesenteric glands. No abnormality in testicles or epididymis. No scar on penis. Purulent bronchitis and slight acute bronchiectasis with purulent nodules of peribronchial consolidation becoming confluent by an intervening red fibrinous pneumonia throughout the right lower lobe and in lower and posterior border of right upper lobe. The post-mortem Wassermann reaction was positive."

Secondary Carcinoma of Jejunum

J. H., aged 68, was admitted with a long history of abdominal pain and flatulence. Two years before she had an attack of abdominal pain and vomiting. This was associated with sweating, and the pain caused her to double up. The attack was followed by jaundice with dark urine and pale motions. Similar attacks occurred three months, and again six weeks, before admission. Nine days previously an even more severe attack occurred in which there was slight jaundice and pale stools. The vomiting had become persistent in the last 26 hours and the vomit had begun to smell. She had passed no flatus for four days, and her bowels had not been opened since the persistent vomiting started.

On admission she had a temperature of 98° F. and a pulse of 128. There was some distension of the abdomen and slight tenderness in the right lumbar region. The patient was very fat, and it was difficult to elicit any further signs. An enema was administered with a large fæcal result but no flatus was passed. Her stomach was washed out prior to operation. A diagnosis of obstruction due to gall-stones was made and immediate operation decided upon.

Operation.—Right paramedian incision. Great distension of the first 6 feet of intestine terminating at a nodular constriction which felt very hard. Secondary nodules on the peritoneum. The growth, together with the adjacent gut, was brought out as a loop and the mesentery was transfixed with a spigot. The loop of gut was incised and a rubber tube passed upwards was sutured and invaginated inwards forming a jejunostomy. It was decided to perform this operation because of the fæcal vomiting and the marked distension of the proximal gut. The tube discharged well after the operation, but it became loose and was removed on the fifth day. On the eleventh day after the first operation her general condition was good, her temperature normal, and her pulse 88, and it was decided to perform the second stage of the operation.

Second Operation.—The protruding loop with the jejunostomy and growth were removed with the cautery, and the clamped extremities of gut were tied with silk ligatures. The abdomen was then reopened and the ligatured ends of the gut embedded with purse-string sutures. A lateral anastomosis was performed, and a drainage-tube was passed through the abdominal wall, which was then sutured.

The patient appeared to do well, but collapsed on the second day.

Pathological Reports.—The report on the specimen removed stated that there was a greyish-white nodule at the mesenteric border of the gut, partially encircling the intestine and producing marked constriction at this point. Microscopically it was seen to consist of secondary tubular and columnar-celled carcinoma invading the small intestine.

The post-mortem report was as follows: "General fibrino-purulent peritonitis. Carcinoma of the gall-bladder. Almost pure cholesterin calculus (2.3 by 1.7 cm.) filling thin fibrous walled gall-bladder. Moderately firm, partly medullary, white, coarsely granular carcinomatous infiltration of fundus of gall-bladder (3 by 2 cm.). Soft polyp of medullary growth projecting into lumen of gall-bladder and adherent to stone. Nodular carcinomatous infiltration of omentum where adherent to fundus of gall-bladder with formation of lump of secondary carcinoma (about 4.5 cm. in diameter). Carcinomatous infiltration extending from this secondary mass through peritoneum and slightly into muscularis of hepatic flexure of colon causing slight constriction of colon at this point. Small ill-defined secondary nodules in peritoneum of mesentery, especially ileocæcal angle and ascending colon. Secondary carcinomatous nodule in peritoneum of lesser curve of pyloric canal invading muscularis. Tough creamy-white nodule in left round ligament at internal abdominal ring. No secondaries in Douglas's pouch nor in liver or any gland. Numerous fat necroses in pancreas. Intact lateral anastomosis 4¼ feet below duodenojejunal flexure. Distension of small intestine above anastomosis."

Comment

Syphilis of the alimentary tract, except at its commencement and its termination, is an exceedingly rare condition. A stricture in the small intestine leading to such obstruction as in the first case is extremely uncommon because the fluidity of the contents usually results in the obstruction giving few symptoms. Therefore the rarity of the case when due to syphilis must be established. I can find no such case recorded in the literature, and surgical text-books do not mention the possibility. Another feature of the case was the presence of gummatous glands in the mesentery and at the time of the operation this led to the belief that the case was one of carcinoma with secondary deposits in the glands.

The second case is interesting in that a carcinoma of the gall-bladder, small in itself and with no secondaries in the glands or liver, gave rise to constriction affecting the gut both in the large and small intestine. At the time of operation the ring carcinoma in the jejunum was thought to be primary and the mass near the liver to be secondary, whereas the reverse was the true state of affairs. Cases in which a secondary nodule of carcinoma causes an obstruction of the small intestine must be extremely uncommon, especially so closely simulating a primary growth.

The question of *treatment* in these two cases presented difficulties which were not surmounted. It was decided to do a jejunostomy in each case because of the enormous distension above the stricture, in the hope that drainage of the intestine would relieve the acute obstruction and allow secondary excision of the stricture and anastomosis to be performed later. In the first case the patient became rapidly dehydrated and died rapidly. In the second, the additional operation was performed but the patient died rapidly of general peritonitis although the anastomosis was intact and every care was taken to prevent the spread of infection from the wound. Despite the fatal results, however, it is felt that the principle of drainage of the gut is a right one. The alternative method embodying this principle would be to resect the infected portion of the gut and effect a lateral anastomosis by the introduction of a tube for drainage of the jejunum above the anastomosis. This would be done after the method of a Witzel's gastrostomy and would not entail a further operation for its closure. End-to-end anastomosis in such cases appears to be impracticable.

because of the great difference in thickness of the walls of the proximal and distal segments of the intestine The alternative method has the disadvantage of prolonging the operation in unsuitable subjects and the risk of leakage is necessarily increased

In the first case the findings were a complete surprise as the history and the radiographic examination suggested an obstruction of the large intestine In the second case diagnosis of obstruction due to a gall-stone was made, but it was never imagined that it had been produced in such a circuitous way

In conclusion I wish to thank Mr H S Souttar and Mr Russell Howard, in whose beds these patients were, for permission to publish this account

A CASE OF
TUBERCULOUS SALPINGITIS ASSOCIATED WITH ACUTE GONORRHŒA

By Margaret Salmond, M D , B S Lond ,
THIRD ASSISTANT, GYNÆCOLOGICAL UNIT, ROYAL FREE HOSPITAL

The following case shows some unusual features —

The patient was an unmarried girl clerk, aged 18, and was admitted to the Royal Free Hospital on May 15th, 1925, complaining of pain in the lower abdomen and vaginal discharge The pain was of a sharp and shooting character, and worse on the left side of the abdomen About April 5th she had noticed abdominal pain and vaginal discharge, that was a few days after admitted misconduct, and a fortnight later she was sent to the infirmary where, after a week's local treatment, a right Bartholin's cyst was excised On leaving the infirmary she had pain in the left groin She was sent up to the V D Department at the Royal Free Hospital for treatment A diagnosis of acute gonorrhœa and gonococcal salpingitis was made, and she was sent to one of the hostels in connexion with the department

The findings then were as follows She had a profuse purulent vaginal discharge, the cervix and urethra were inflamed, and there were some hard and nodular lymphatic glands in the groin. There was an indefinite tender mass on the left side of the pelvis, and the uterus was not palpable apart from the mass The rectum and anus were normal The menstrual history showed no abnormality until the onset of illness, since then there had been amenorrhœa The onset of periods was at 15 years, the periodicity 3–4 days every 28 days, the loss rather profuse The circulatory and respiratory systems were normal There was no past illness except measles, but there was a well-marked family history of tuberculosis Films from the cervix and urethra showed much fresh pus and organisms resembling gonococci, and the Wassermann reaction was negative She had a temperature of 101° F and a pulse of 112 She was seen again on May 15th and found to have generalised abdominal tenderness and involvement of both tubes, and was admitted to hospital

Condition on admission She had a temperature of 99° and pulse 96, and was rigid over the left lower abdomen and tender all over the abdomen, especially on the left side Vaginal examination showed both tubes swollen and tender She was treated with belladonna fomentations to the abdomen and hot douches of 2 per cent potassium permanganate The abdominal pain improved on this treatment, and it was decided to operate if possible when the temperature was quiescent The temperature remained irregular for 10 days, the maximum being a rise to 101 8° After this, for a further period of seven days, the temperature became more swinging in character with a well-marked 6 P M rise and then settled down to normal for three days previous to operation Urethral films taken during this period showed pus and gonococci At the operation the findings were as follows The sigmoid colon was adherent to the bladder, left tube and ovary These adhesions were separated, and a small abscess was opened which had been enclosed by them. There was pus also in the pouch of Douglas The pus was thick, yellow and blood-stained The left ovary was much enlarged and dark in colour The left tube was thickened, inflamed, and adherent to the ovary by its fimbriated end The uterus was normal but infantile in type The right ovary was normal The right tube was slightly thickened and inflamed, but patent A left salpingo-oöphorectomy was done The pelvis was swabbed out with collosal argentum, and the wound closed without drainage The ovary on section showed a blood cyst and a degenerate corpus luteum The tubes were not patent The pathological report on sections from both tube and ovary showed well-marked tuberculosis The pus from the peritoneal cavity was sterile and contained polymorphonuclear and mononuclear cells The temperature after operation was irregular for four days, and then began to swing again, the maximum rise being at 6 P M , and the maximum height 103° The rise gradually decreased, and settled to normal on the sixteenth day following operation Treatment for gonorrhœa was resumed on the eighth day after operation Saline and 2 per cent lactic acid douches were given, and the urethra painted with 5 per cent mercurochrome Films taken from the urethra four days after treatment showed some pus and gonococci Films taken on discharge, from urethra showed much fresh pus and no gonococci, from the cervix, epithelial cells, a few pus cells and no gonococci

The abdominal tenderness gradually disappeared, and the wound healed by first intention.

On discharge the patient had still an erosion of cervix and some vaginal discharge but her general health was good, and she was afebrile She was transferred to Whipp's Cross Infirmary for open air treatment for tuberculosis and local treatment for gonorrhœa

I am indebted to Dr Vaughan Sawyer and Dr Margaret Rorke for permission to publish this case

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY

At a special meeting of this Section held on Jan 19th Mr V Warren Low, the President, took the chair, and Prof M T Finney, of the Johns Hopkins Hospital, Baltimore, read a paper on the

Pathogenesis of Gastric and Duodenal Ulcer, with a a consideration of the general rules of treatment Prof Finney began by surveying research into the subject from the investigations of Matthew Baillie (1793) and Abercrombie (1824) until recent times The origin and persistence of gastric ulcer, he said, had been a source of much speculation and experiment and most observers had agreed that the action of gastric juice played an important part in the development and continuance of ulceration Still, the action of gastric juice alone was not sufficient in itself to start ulceration in normal gastric mucosa nor did it prevent the rapid healing of artificially produced defects when the blood-supply had not been interfered with Ninety-eight per cent of ulcers of stomach and duodenum were in the region of the pylorus, the posterior part of the lesser curvature the pyloric antrum, and the first part of the duodenum —i e , in the parts supplied by the right gastric artery and its supraduodenal branch There seemed to be a relationship between these two facts If the narrow margin of safety in the human being was encroached upon by an injury to the mucosa, the eroding action of the gastric juice probably sufficed to develop a chronic ulcer Prof Finney proceeded to review the various theories of causation—inflammatory, neurogenic, circulatory bacterial, digestive, and corrosive

Malignant Transformation of Ulcers

Cruveilhier in 1829 had been the first to suggest that these ulcers might take on a malignant transformation, went on Prof Finney, the matter was of importance because the extent of a surgeon's belief in the possibility of such change would influence his decision what operation to employ The percentage of cases in which malignant change had occurred in a simple ulcer appeared to have varied from 5 to 2½, and there must, therefore, be standardised criteria in order that comparisons could be made There were certainly well authenticated cases in which carcinoma had been preceded by a long history of ulcer In 799 cases operated upon at the Mayo Clinic for gastric ulcer, 4 1 per cent died of cancer during the seven-year period, while in 1610 cases quoted by Ewing the frequency was 2 2 per cent though it was thought that in some of these the lesion had been malignant from the start

Operative Treatment

A plastic operation on the pylorus, continued Prof Finney, had first been carried out in 1886 by Heineke, and in the following year it had been done by Mikulicz Kocher's side-to-end gastro-duodenostomy following pylorectomy was reported in 1891 In 1885 it was considered that the right treatment for gastric ulcer was medical but Welch, writing in that year, admitted that resection of gastric ulcers which resisted all other methods of treatment was a justifiable operation Surgical treatment was largely advanced by the idea that ulcers might become carcinomatous, as well as by the grave danger of hæmorrhage, perforation or obstruction Radiography had helped to establish a definite syndrome Operations for ulcer of the stomach could be classed as either conservative or radical. The first group was further divisible into (1) procedures directed to local excision, cauterisation or suture of the ulcer; (2) local excision plus gastroenterostomy or pyloroplasty, (3) gastroenterostomy or pyloroplasty alone An operation was radical when not only the ulcer, but also the part of the stomach which developed 90 per cent of the ulcers was removed In his choice of the operation in a given case the surgeon should be largely influenced by the condition of his patient and his ability to withstand hæmorrhage or perforation with resultant shock Such local conditions as dense adhesions would have a limiting effect on the operation If operation were done in the quiescent stage the patient's condition would not loom so large and in that case the opinion formed about the operation needed would depend on (1) the importance of removing the ulcer-bearing part of the stomach, (2) the efficacy of reducing the acidity by a large resection (3) the possibility of carcinomatous degeneration

Pre-operative Preparation

Unless the operation was to be for the relief of urgent conditions, said Prof Finney, each patient should be carefully prepared *beforehand for this* reduced infection to a quite negligible quantity The routine practised in his hospital included frequent antiseptic cleansing of the *teeth*, prescription of a sterile diet (cooked foods, pasteurised or boiled milk eggs, orange-juice boiled water, &c) and, if gastric stasis was present, lavage of the stomach once or twice a day. It was found that the acid stomach would sterilise itself in 48 hours provided no infecting matter was meanwhile ingested This did not apply, however to ulcerating carcinoma of the walls of the stomach, the *Streptococcus pyogenes* being commonly found in these cases Efforts to sterilise the gastro-intestinal tract by drugs had been futile Careful physical examination of patients should never be omitted, unless the urgency for operation was very great Starved and dehydrated patients should first be brought *into* an improved condition With regard to the anæsthetic, the claims of local as against general anæsthesia should be carefully weighed, for regional nerve-block had given excellent results, though it required a thoroughly capable administrator In the actual operation it was necessary to pay scrupulous attention to details of technique and of asepsis, the tissues must be gently handled and undue haste avoided Each surgeon probably had a favourite operation, but he should not permit himself to make use of it on every occasion, as to do so was to court disaster

Summary

Summarising his views, Prof Finney said that no surgical procedure should be carried out on the stomach without previous consultation with a competent physician Resection of an ulcer *did not mean* that it would not recur As a general rule pyloroplasty or gastroduodenostomy associated when possible with resection of the ulcer would be his method of choice This relegated gastroenterostomy and extensive gastric resection to subordinate places. Still from inability to mobilise the duodenum satisfactorily, pyloroplasty was not always a practical proposition When extensive resection of the pyloric part of the stomach was indicated gastroduodenostomy by the Harberer-Finney method was the operation of choice when it could be done In the presence of malignant disease, if operation was indicated at all, the most radical possible procedure was really in effect the most conservative This principle was not the guide, however, in benign conditions, and indeed the reverse was true

Discussion

Sir **Anthony Bowlby** proposed a cordial vote of thanks to Prof Finney and referred to his distinction in all branches of general surgery; at the same time he expressed his high appreciation of Prof Finney's activities in France during the late war, when he served as Chief Medical Adviser to the American Army

Sir **James Berry** (President of the Royal Society of Medicine) seconded this vote of thanks, which was carried with acclamation

Dr **Leon Jona** (Melbourne) gave his views on the pathogenesis of duodenal ulcer, recounting some experiments he had performed on dogs On tying the main pancreatic duct he found that duodenal ulcer resulted every time, and his research had convinced him that diminution or absence of the normal pancreatic juice was a factor in the pathogenesis of gastroduodenal ulcer The usual situation of the ulcers bore out this view

Mr. E R **Flint** (Leeds) agreed with Prof Finney about the superiority of gastroduodenostomy to gastroenterostomy He had himself operated on nearly 200 such cases, and in only nine of them had he failed to mobilise the duodenum. His technique differed somewhat from that of Prof Finney, as he made his anastomosis in the second part and he did not use a clamp on the *duodenum* nor excise the mucosa Also, he did not take in gastric mucosa with the inner stitch if it could be avoided

Mr F A. **Jeans** (Liverpool) spoke of a series of 36 cases of hour-glass stomach with a 15 years' history; in this series only two were malignant which showed how unlikely it was that even long-standing ulcer would result in malignant degeneration He also referred to a class of people who whatever was done for them, were persistent ulcerators and perforators

Mr R P **Rowlands** said that he believed obstruction in the duodenum to be an important cause of these ulcers On the continent and to some extent in this country, there was at present a wave of enthusiasm which led to surgeons doing too much personally, he could never see the advantage of performing partial gastrectomy for simple ulcer and the mortality from this operation was much too high. For many years he had been a strong believer in Prof Finney's operation He had been very pleased to hear him insist on the importance of adequate preparation of patients before operation

Mr A. J **Walton** agreed that there was a tendency to do too much operatively for gastric and duodenal ulcer. Partial gastrectomies were mostly not only wrong and dangerous, but were also unnecessary These ulcers were a disease peculiar to civilised man Up to last June he had had 317 cases of ulcer of the lesser curvature 305 of ulcer of the duodenum 165 pyloric ulcers—figures which did not support the view that in cases of ulcer there was some peculiarity in the anatomy of the duodenum. A Hurst had drawn attention to the importance of hyperacidity, and had pointed out that in some individuals this was associated with a congenital malformation: Mr Walton attached considerable importance to this factor in the ætiology He thought it was definitely increased by the modern over-indulgence in cigarettes Carcinomatous degeneration occurred in so small a proportion of ulcers that there seemed no warrant for carrying out large gastrectomies on account of that fear For hour-glass stomach he did a wide wedge-resection; if that was not possible he resorted to partial gastrectomy

Prof C A **PANNETT** said that none of the ulcers produced in animal experiments were identical with those found in the human being In man the ulcers owed their origin, he believed, to a specific organism which had not yet been discovered, and a requisite condition for the formation of ulcer was a combination of pyloric and intestinal secretions He considered that the pyloric end of the stomach was the region at fault Sometimes ulcers formed in Meckel's diverticulum and perforated, they were peptic ulcers The infection came from the intestinal canal, not from the blood stream.

Mr **HERBERT PATERSON** believed that there was no dependable evidence that in even 5 per cent of cases a simple ulcer assumed a malignant form If even 5 per cent did so, it would be expected that a considerable number of people operated on for simple ulcer would die of carcinoma, but that was not the fact

Reply

Prof **FINNEY**, in reply, said that he did not feel that he was an enthusiast, he did not do pyloroplasty every time he opened an abdomen But his experience had shown him that it was the best method whenever it was feasible and practicable In 85 per cent of his cases he had been able to do it with satisfaction When there seemed likely to be any tension, a thing to be carefully avoided in the abdomen, he desisted and carried out gastroenterostomy For indurated ulcer he did a wide resection Surgery demanded as clear and accurate a diagnosis as all the resources at command made possible, it should be the resultant of the best skill of the radiologist and physician as well as of the surgeon, and every test likely to be of value must be used When, on opening the abdomen, he found no demonstrable, palpable lesion, he did nothing He thanked Dr Jona for his suggestion, which might be fruitful, on arriving home he would go into the question He concluded with a word of gratitude to Sir Anthony Bowlby and the staff under him for the kindly cooperation shown to him and his colleagues in France on the entry of the American Army into the war

SECTION OF OBSTETRICS OF THE ROYAL SOCIETY OF MEDICINE AND MEDICO-LEGAL SOCIETY.

THE ETHICAL, LEGAL, AND MEDICAL ASPECTS OF ABORTION

A JOINT meeting of the Section of Obstetrics of the Royal Society of Medicine and the Medico-Legal Society was held on Jan 21st, Lord Justice **SALTER** in the chair

The discussion was opened by Dr J S **FAIRBAIRN** and Lord **RIDDELL**, whose papers are published on pages 217 and 219 respectively

Dr **RUSSELL ANDREWS** apologised for the absence owing to influenza of Dr T **WATTS EDEN**, whose place he had been asked to fill at the last moment He agreed in the main with Dr Fairbairn, but said that it was an exaggeration to state that the old indication for abortion—danger to the life and health of the mother—had been thrown over. He also disagreed with the suggestion that, in many cases where abortion was proposed to consultants, there had not been a fair trial of medical means of relieving the distressing symptoms In most cases the patient's medical attendant had made attempts to get rid of the troubles before considering abortion Otherwise he thought Dr Fairbairn had put the case very fairly, and had suggested the difficulties in which an honest man might find himself in trying to do the best for his patient and yet keep within the law Cases brought to the specialist by a doctor usually required a great deal of consideration, but cases that came on their own were very often easily dealt with The patient and her husband were usually unaware that there was any legal bar to induction of abortion, and a few minutes' commonsense conversation would convince both that there was no indication A small number had to be told that the doctor could have nothing more to do with their case, and in a few more cases it was clear that continuation of the pregnancy must mean danger to life or health

Borderline Cases

The borderline cases were very difficult, some of the most difficult a consultant ever had to deal with He sympathised very much with the patient—generally a tired, anxious, excited woman who felt that she could not go on, not necessarily from selfish motives, but for the sake of her husband and children, to whom she would be very little use for many months It was necessary to guard against being swayed too much by sympathy Another factor was the fixed idea in the minds of many husbands and wives that pregnancy was very dangerous, often the patient had been told by doctor or midwife that she must never become pregnant again When he (the speaker) had considered that this advice had been given lightly he had remarked that there was a difference between advising against a future pregnancy and agreeing to destroy a life that had been begun. The answer he received was "There would not be such a difference if only doctors would be more logical" When the question was one of impairment of health the difficulty that arose was the difference of opinion as to how serious and how permanent the damage to health must be to justify abortion Cases could only be judged on their merits The consultant longed for a definite peg on which to hang his decision

Dr Andrews quoted two examples of the borderline case in which he had considered termination of the pregnancy justifiable

CASE 1 —A lady of 37 had had five children, the last three being at that time aged 4, 2½, and 1 respectively She had had very poor health during the previous pregnancy, being almost an invalid Her doctor had strongly advised her against having another child on account of the strain Her health for the last 12 months had been very poor, though there was no organic disease, and her symptoms, though neurasthenic, were very real to her She was two months' pregnant and her health had greatly deteriorated in that time She was haggard, anxious, losing weight, suffering from insomnia, severe nausea, and considerable tinnitus She was devoted to her children and said she felt she could not look forward to another year of invalidism during which she could take very little part in their upbringing or be any companion to her husband

CASE 2 —A poor woman of 43 had had five pregnancies; three had gone to term and of these children one had died and two were delicate, she had had two spontaneous abortions at 4½ and 5½ months respectively Throughout all the pregnancies she had been very largely confined to bed, chiefly through uncontrollable retching She had never been in good health, but during her pregnancies she could not look after her family or do her work She had very poor physique and weighed under 7 st At the time of examination she was 2½ months' pregnant and again had vomiting and retching

In these cases it had not been possible to say exactly what damage would be done to the patient's health by continuation of pregnancy, and there was no danger to life Nevertheless he had felt he could satisfy his own conscience and make a fair show before any tribunal

Medical Responsibility to the Law

Sir **TRAVERS HUMPHREYS** said that those responsible for the terms of the debate had divided the subject into three parts—ethical, medical, and legal From his point of view, however, it divided itself into two abortion which was criminal and abortion which was not criminal By lawful abortion he meant the steps taken by a qualified medical man to get rid of a condition in his patient which he considered, using the best of his skill and ability, and of course honestly, on medical grounds and on medical grounds alone, to be dangerous to the safety of the patient He used the word "safety" advisedly, because the purely medical question was not one with which the law was concerned No doctor who had used the best of his skill and judgment in the sole interest of his patient need imagine for a moment that the law would call him to account It had been stated, and truly stated, that under such circumstances the sole concern of the medical man was the welfare of his patient and that welfare was her medical and not her social or economic welfare He agreed with Lord Riddell and Dr. Fairbairn that the doctor should confine himself to the medical question It might be that the patient who was asking for abortion might herself be considering such results of her pregnancy as a diseased child or disgrace to herself but these were matters in which a doctor at that stage was in no way concerned They might well form the subject of advice to his patient at other times, but when once the condition of pregnancy had arisen the golden rule must be that the doctor was not entitled to consider anything but the health and future of his patient on medical grounds When a doctor in the exercise of his discretion had decided to induce abortion there was no question of law or ethics Under what conditions and in the presence of what symptoms a doctor was entitled to take the extreme step of interfering with the ordinary course of Nature was a very interesting matter for medical men and for the intelligent man in the street but it would be an impertinence for one who claimed no medical knowledge to express any views

Criminal Abortion.

When we turned to the question of criminal abortion, said Sir Travers Humphreys we plunged at once into the realm of law and ethics. The legal question was extraordinarily simple In this country for a very long time, criminal abortion had been regarded as a very serious offence In the United States, in France, and in Belgium, to the best of his knowledge the law was very similar to our own In the Belgian penal code there was a provision that any person who caused abortion even without desiring to do so, was liable to extremely heavy punishment if he had been guilty of violence or ill-treatment Those who looked at French journals might be disposed to doubt whether the practice of abortion was regarded in France with quite the same distaste that it was in this country, but the tone of the journals had no bearing on the law In a civilised country criminal abortion would never be found regarded as other than grossly improper and in the last degree punishable. What Dr Fairbairn had remarked about the approval of the practice by the Soviet Government did not affect this observation, he had used the term "civilised" country It was he supposed, universally recognised that the practice of abortion and any operation or means to that end taken by any other than a highly qualified and skilful person must be a source of the greatest possible danger to the woman concerned It must needs be an intolerable burden to the medical profession if the doctor had to say on other than medical grounds whether he was to relieve a woman of her condition. There was no doubt that the increasing prevalence of the crime in this country was very largely due to the widespread belief that abortion at any rate in the early stages of pregnancy, might be induced without any risk to the woman concerned He had heard Sir Bernard Spilsbury state in the witness-box that he entirely disagreed with that idea, and that there was no such thing as safely-procured abortion If that were so, Sir Travers hoped that medical men would lose no opportunity of impressing the fact upon those whom they might think likely to be under a misapprehension as to the danger of the practice

The Ethical Aspect

He supposed that by ethics was meant in this connexion that branch of philosophy that dealt rather with things as they ought to be than as they were with rules of conscience rather than with rules of law It might be said that it must be ethically wrong wilfully and intentionally to break the laws of one's country, but he was not so sure about it Even at the risk of being considered a very immoral person, he would say that there might be, and had been, cases in which it was very difficult if not impossible to attribute any moral blame to a person who had helped a girl out of her trouble. He quoted as an example a case recently heard at the Central Criminal Court where a French girl had refused repeated offers of marriage from the young father of her child, had refused his offer to send her back to France for the confinement, and had insisted on procuring abortion, telling him that if he would not help her she would go to her girl friends who would He had asked the advice of a much older man who had assured him that it was a simple matter and had referred him to a "doctor" for the operation The girl had died of peritonitis and the doctor the young man and his friend were all charged with manslaughter The judge refused to punish the lad with a day's imprisonment, and he (Sir Travers) was glad of it It was difficult to regard that young man as having done anything but what most men would say was right under the circumstances Anybody who deliberately made up his mind to break the law must be prepared to take the consequences but if he were able to prove that his motives and intentions were above suspicion and that he had acted from the dictates of his conscience, he had not much to fear, for our judges were men before they were judges and judges were and remained, very human

Pregnancy and Tuberculosis

Dr HALLIDAY SUTHERLAND said that while gynæcologists mentioned tuberculosis as a very probable indication for abortion, the question did not loom large in the minds of those who were chiefly concerned in the treatment of tuberculosis Tuberculosis had no constant influence on pregnancy and pregnancy had no constant influence on the course of tuberculosis Everyone knew cases where a woman suffering from the disease brought forth a healthy child where pregnancy was associated with an increase in the disease and where it was accompanied by an amelioration so marked that the physician was led to give an unduly favourable prognosis Figures from the Stockholm Maternity Centre had been published dealing with the influence of pregnancy on the expectation of life of the tuberculous woman. In 203 pregnant diseased women and 396 non-pregnant the results at the end of a year showed that of the pregnant 12 8 per cent were dead, of the non-pregnant 14 6 per cent. Two years later 26 per cent of the pregnant had died and 30 per cent of the non-pregnant On these figures the tuberculous woman who became pregnant had a better expectation of life than the woman who did not Other figures showed that pregnancy in the second stage exerted an unfavourable effect on 12 per cent of tuberculous women. Gynæcologists were at complete variance; some had statistics showing that the aborted lived longer some that they died sooner, but their statistics had the disadvantages that they did not specify the stage of the disease and the early and late stages were not comparable. It must be remembered that a very early diagnosis of tuberculosis might be of considerable value to those who desired for non-medical reasons to arrange an unimpeachable, unassailable abortion He asked whether the profession was prepared to prolong the lives of 12 tuberculous women by paying the price of killing one hundred fœtuses He hoped the medical sanctions for abortion would be curtailed and not extended since it was at best an act of despair and at worst a crime akin to murder. If any section of the profession were carried away by the wave of criminal sentimentality that was passing over the country, their activities might well be checked by making abortion notifiable

The Rights of the Mother

Earl RUSSELL said he did not disagree with the criteria Dr Fairbairn had laid down, but it did strike him that there was no legal warrant for excusing the felony of abortion on the grounds that the patient's health would be improved by it The

Prof C A PANNETT said that none of the ulcers produced in animal experiments were identical with those found in the human being In man the ulcers owed their origin, he believed, to a specific organism which had not yet been discovered, and a requisite condition for the formation of ulcer was a combination of pyloric and intestinal secretions He considered that the pyloric end of the stomach was the region at fault Sometimes ulcers formed in Meckel's diverticulum and perforated, they were peptic ulcers The infection came from the intestinal canal, not from the blood stream

MR HERBERT PATERSON believed that there was no dependable evidence that in even 5 per cent of cases a simple ulcer assumed a malignant form If even 5 per cent did so, it would be expected that a considerable number of people operated on for simple ulcer would die of carcinoma, but that was not the fact

Reply

Prof FINNEY, in reply said that he did not feel that he was an enthusiast, he did not do pyloroplasty every time he opened an abdomen But his experience had shown him that it was the best method whenever it was feasible and practicable In 85 per cent of his cases he had been able to do it with satisfaction When there seemed likely to be any tension, a thing to be carefully avoided in the abdomen, he desisted and carried out gastro-enterostomy For indurated ulcer he did a wide resection Surgery demanded as clear and accurate a diagnosis as all the resources at command made possible, it should be the resultant of the best skill of the radiologist and physician as well as of the surgeon, and every test likely to be of value must be used When, on opening the abdomen, he found no demonstrable, palpable lesion, he did nothing He thanked Dr Jona for his suggestion, which might be fruitful, on arriving home he would go into the question He concluded with a word of gratitude to Sir Anthony Bowlby and the staff under him for the kindly cooperation shown to him and his colleagues in France on the entry of the American Army into the war

SECTION OF OBSTETRICS OF THE ROYAL SOCIETY OF MEDICINE AND MEDICO-LEGAL SOCIETY

THE ETHICAL, LEGAL, AND MEDICAL ASPECTS OF ABORTION

A JOINT meeting of the Section of Obstetrics of the Royal Society of Medicine and the Medico-Legal Society was held on Jan 21st, Lord Justice SALTER in the chair

The discussion was opened by Dr J. S FAIRBAIRN and Lord RIDDELL, whose papers are published on pages 217 and 219 respectively

Dr RUSSELL ANDREWS apologised for the absence owing to influenza of Dr T WATTS EDEN, whose place he had been asked to fill at the last moment He agreed in the main with Dr Fairbairn, but said that it was an exaggeration to state that the old indication for abortion—danger to the life and health of the mother—had been thrown over He also disagreed with the suggestion that, in many cases where abortion was proposed to consultants, there had not been a fair trial of medical means of relieving the distressing symptoms In most cases the patient's medical attendant had made attempts to get rid of the troubles before considering abortion Otherwise he thought Dr Fairbairn had put the case very fairly, and had suggested the difficulties in which an honest man might find himself in trying to do the best for his patient and yet keep within the law Cases brought to the specialist by a doctor usually required a great deal of consideration, but cases that came on their own were very often easily dealt with. The patient and her husband were usually unaware that there was any legal bar to induction of abortion, and a few minutes' commonsense conversation would convince both that there was no indication A small number had to be told that the doctor could have nothing more to do with their case, and in a few more cases it was clear that continuation of the pregnancy must mean danger to life or health

Borderline Cases

The borderline cases were very difficult, some of the most difficult a consultant ever had to deal with He sympathised very much with the patient—generally a tired, anxious, excited woman who felt that she could not go on, not necessarily from selfish motives, but for the sake of her husband and children, to whom she would be very little use for many months It was necessary to guard against being swayed too much by sympathy Another factor was the fixed idea in the minds of many husbands and wives that pregnancy was very dangerous, often the patient had been told by doctor or midwife that she must never become pregnant again When he (the speaker) had considered that this advice had been given lightly he had remarked that there was a difference between advising against a future pregnancy and agreeing to destroy a life that had been begun The answer he received was " There would not be such a difference if only doctors would be more logical " When the question was one of impairment of health the difficulty that arose was the difference of opinion as to how serious and how permanent the damage to health must be to justify abortion Cases could only be judged on their merits The consultant longed for a definite peg on which to hang his decision

Dr Andrews quoted two examples of the borderline case in which he had considered termination of the pregnancy justifiable

CASE 1 —A lady of 37 had had five children, the last three being at that time aged 4, 2½, and 1 respectively She had had very poor health during the previous pregnancy, being almost an invalid Her doctor had strongly advised her against having another child on account of the strain Her health for the last 12 months had been very poor, though there was no organic disease, and her symptoms, though neurasthenic, were very real to her She was two months' pregnant and her health had greatly deteriorated in that time She was haggard, anxious, losing weight, suffering from insomnia, severe nausea, and considerable tinnitus She was devoted to her children and said she felt she could not look forward to another year of invalidism during which she could take very little part in their upbringing or be any companion to her husband

CASE 2 —A poor woman of 43 had had five pregnancies, three had gone to term and of these children one had died and two were delicate, she had had two spontaneous abortions at 4½ and 5½ months respectively Throughout all the pregnancies she had been very largely confined to bed, chiefly through uncontrollable retching She had never been in good health, but during her pregnancies she could not look after her family or do her work She had very poor physique and weighed under 7 st At the time of examination she was 2½ months' pregnant and again had vomiting and retching

In these cases it had not been possible to say exactly what damage would be done to the patient's health by continuation of pregnancy, and there was no danger to life Nevertheless he had felt he could satisfy his own conscience and make a fair show before any tribunal

Medical Responsibility to the Law

SIR TRAVERS HUMPHREYS said that those responsible for the terms of the debate had divided the subject into three parts—ethical, medical, and legal From his point of view, however, it divided itself into two abortion which was criminal and abortion which was not criminal By lawful abortion he meant the steps taken by a qualified medical man to get rid of a condition in his patient which he considered, using the best of his skill and ability, and of course honestly, on medical grounds and on medical grounds alone, to be dangerous to the safety of the patient He used the word " safety " advisedly, because the purely medical question was not one with which the law was concerned No doctor who had used the best of his skill and judgment in the sole interest of his patient need imagine for a moment that the law would call him to account It had been stated and truly stated that under such circumstances the sole concern of the medical man was the welfare of his patient and that welfare was her medical and not her social or economic welfare He agreed with Lord Riddell and Dr Fairbairn that the doctor should confine himself to the medical question It might be that the patient who was asking for abortion might herself be considering such results of her pregnancy as a diseased child or disgrace to herself, but these were matters in which a doctor at that stage was in no way concerned They might well form the subject of advice to his patient at other times, but when once the condition of pregnancy had arisen the golden rule must be that the doctor was not entitled to consider anything but the health and future of his patient on medical grounds When a doctor in the exercise of his discretion had decided to induce abortion there was no question of law or ethics Under what conditions and in the presence of what symptoms a doctor was entitled to take the extreme step of interfering with the ordinary course of Nature was a very interesting matter for medical men and for the intelligent man in the street but it would be an impertinence for one who claimed no medical knowledge to express any views

Criminal Abortion

When we turned to the question of criminal abortion, said Sir Travers Humphreys, we plunged at once into the realm of law and ethics The legal question was extraordinarily simple In this country, for a very long time, criminal abortion had been regarded as a very serious offence In the United States in France, and in Belgium to the best of his knowledge the law was very similar to our own In the Belgian penal code there was a provision that any person who caused abortion even without desiring to do so, was liable to extremely heavy punishment if he had been guilty of violence or ill-treatment. Those who looked at French journals might be disposed to doubt whether the practice of abortion was regarded in France with quite the same distaste that it was in this country, but the tone of the journals had no bearing on the law In a civilised country criminal abortion would never be found regarded as other than grossly improper and in the last degree punishable. What Dr Fairbairn had remarked about the approval of the practice by the Soviet Government did not affect this observation , he had used the term "civilised" country It was, he supposed, universally recognised that the practice of abortion and any operation or means to that end taken by any other than a highly qualified and skilful person, must be a source of the greatest possible danger to the woman concerned It must needs be an intolerable burden to the medical profession if the doctor had to say on other than medical grounds whether he was to relieve a woman of her condition. There was no doubt that the increasing prevalence of the crime in this country was very largely due to the widespread belief that abortion at any rate in the early stages of pregnancy, might be induced without any risk to the woman concerned He had heard Sir Bernard Spilsbury state in the witness-box that he entirely disagreed with that idea, and that there was no such thing as safely-procured abortion If that were so, Sir Travers hoped that medical men would lose no opportunity of impressing the fact upon those whom they might think likely to be under a misapprehension as to the danger of the practice

The Ethical Aspect

He supposed that by ethics was meant in this connexion that branch of philosophy that dealt rather with things as they ought to be than as they were with rules of conscience rather than with rules of law It might be said that it must be ethically wrong wilfully and intentionally to break the laws of one's country, but he was not so sure about it Even at the risk of being considered a very immoral person, he would say that there might be, and had been, cases in which it was very difficult, if not impossible to attribute any moral blame to a person who had helped a girl out of her trouble He quoted as an example a case recently heard at the Central Criminal Court where a French girl had refused repeated offers of marriage from the young father of her child, had refused his offer to send her back to France for the confinement, and had insisted on procuring abortion telling him that if he would not help her she would go to her girl friends who would He had asked the advice of a much older man, who had assured him that it was a simple matter and had referred him to a "doctor" for the operation The girl had died of peritonitis and the doctor, the young man and his friend were all charged with manslaughter The judge refused to punish the lad with a day's imprisonment, and he (Sir Travers) was glad of it It was difficult to regard that young man as having done anything but what most men would say was right under the circumstances Anybody who deliberately made up his mind to break the law must be prepared to take the consequences, but if he were able to prove that his motives and intentions were above suspicion and that he had acted from the dictates of his conscience, he had not much to fear, for our judges were men before they were judges and judges were, and remained, very human

Pregnancy and Tuberculosis

Dr **HALLIDAY SUTHERLAND** said that while gynæcologists mentioned tuberculosis as a very probable indication for abortion, the question did not loom large in the minds of those who were chiefly concerned in the treatment of tuberculosis Tuberculosis had no constant influence on pregnancy and pregnancy had no constant influence on the course of tuberculosis Everyone knew cases where a woman suffering from the disease brought forth a healthy child where pregnancy was associated with an increase in the disease and where it was accompanied by an amelioration so marked that the physician was led to give an unduly favourable prognosis Figures from the Stockholm Maternity Centre had been published dealing with the influence of pregnancy on the expectation of life of the tuberculous woman In 203 pregnant diseased women and 396 non-pregnant the results at the end of a year showed that of the pregnant 12 8 per cent were dead, of the non-pregnant 14 6 per cent. Two years later 26 per cent of the pregnant had died and 30 per cent of the non-pregnant On these figures the tuberculous woman who became pregnant had a better expectation of life than the woman who did not Other figures showed that pregnancy in the second stage exerted an unfavourable effect on 12 per cent of tuberculous women Gynæcologists were at complete variance; some had statistics showing that the aborted lived longer, some that they died sooner, but their statistics had the disadvantages that they did not specify the stage of the disease and the early and late stages were not comparable It must be remembered that a very early diagnosis of tuberculosis might be of considerable value to those who desired for non-medical reasons to arrange an unimpeachable, unassailable abortion He asked whether the profession was prepared to prolong the lives of 12 tuberculous women by paying the price of killing one hundred fœtuses He hoped the medical sanctions for abortion would be curtailed and not extended, since it was at best an act of despair and at worst a crime akin to murder If any section of the profession were carried away by the wave of criminal sentimentality that was passing over the country, their activities might well be checked by making abortion notifiable.

The Rights of the Mother

Earl **RUSSELL** said he did not disagree with the criteria Dr Fairbairn had laid down, but it did strike him that there was no legal warrant for excusing the felony of abortion on the grounds that the patient's health would be improved by it The practice of gynæcologists had been extended to a degree that amounted to relieving their patients from a very inconvenient time, and which seemed unjustified by the existing law Sir Travers Humphreys had been quite right in saying that there would be no conviction, no jury would find that a doctor had acted unlawfully when he had used his best skill in the interests of the patient This did show how the doctors were the high priests of modern civilisation and above the law, very often there was no appeal to a legal tribunal from their decision. They had to consider solely the interests of their patients, and in so doing they would apply logically to the question of the removal of a fœtus the same tests and the same degree of consideration as they would to the removal of any other tumour It seemed to him that there was something beyond the sole interests of the patient that the doctors had to consider All operations were dangerous, there were some in which the mortality was 50 per cent, and the choice was generally left to the patient It was essential that the law should be correct and unchallengeable, but the ultimate ethical view was not necessarily that on the statute book of the moment He took the general ethical view (said to be so shocking) that in a matter of this sort the mother alone should be the arbiter The child was hers, and she was the person to decide whether the early fœtus was to be disposed of or not The existing legal enactments came on the statute book on religious grounds, and on those grounds they might be defensible but nobody had any right to impose his own religious views on other people He took the view that the mother was the master of the situation, and entitled to decide if she preferred the life of the child or her own life, health or convenience There was an undoubted moral duty on every mother to do her best for her child-to-be and to ensure that it should be as happy and healthy as pre- and ante natal care could make it But the State had no abstract ethical right to interfere with the situation

Prof LOUISE McILROY spoke on the ethical aspect of the problem, and agreed with Dr Fairbairn The development of the fœtus could not be divided into stages, life began with conception and belonged to the State from conception Abortion ought to be notified to the State just as live and stillbirths were She recognised that it was very much easier for the consultant in London to carry out a general ethical programme than for a country practitioner, whose complete ruin might follow a failure to comply with the wishes of an influential patient Women must learn that they could not go into a doctor's consulting-room as if going to a bargain counter Abortion was nothing but homicide, though sometimes it might be justifiable homicide Induction of abortion was a confession of failure She would like very much to have legal permission to induce abortion in a case of rape; she did not think a woman ought to have to continue with a pregnancy forced on her against her will by an unknown person A patient returning for a second or third abortion raised a very difficult question "One patient, one abortion" was the allowance stated, yet the circumstances justifying the first would all be present on the subsequent occasions Doctors aided and abetted abortionists because they were trying to help the patient. If they could get rid of their pledge of secrecy to the patient and get justice done it would be a great help.

Dr F McCANN remarked on the wave of abortion that had passed over Europe since the war, and the Bills tabled in the Parliaments of Germany, Austria, and Switzerland to legalise it in the first three months of pregnancy He urged the meeting to take up a strong position on the ethical aspect Once loopholes were created the whole position fell, and it would be most disastrous to the country not to take a strong line It could not be too well known that there was life from conception onwards and that there was danger and very great danger in abortion at the most skilful hands Even simple dilatation of the cervix might cause very serious consequences, and emptying the womb opened channels to infection which might vitiate the results of the best operator If this were driven home, the number of cases would be limited There was a great deal of confusion about the legal position The Royal College of Physicians of London had once taken Counsel's opinion, which had been that abortion was justifiable to save the mother's life. One peculiarity about the law was that, if a woman attempted to procure abortion on herself, it was a crime if she were pregnant and not a crime if she were not Another was that the punishment was so varied, the death penalty was sometimes pronounced, the judge knowing well that it would not be carried out The law as it stood must be very difficult to administer

Mrs MARIE STOPES, D Sc, expressed surprise and regret, and protested at Dr Fairbairn's statement that the movement for constructive birth control tended to produce a slackening of the moral fibre The ethics of abortion had not yet been touched upon by any speaker in a truly fundamental way, everybody had spoken as if the condition were an exceptional one in which the patient consulted the medical profession and, if they refused abortion, the case was finished Abortion was attempted and going on to a staggering extent throughout the country by other than practitioners of medicine, in an open and bare-faced way that would astonish the meeting One speaker had spoken of his three or four cases who had not realised that there was any legal bar to abortion, she had had ten thousand such cases Over ten thousand persons had written to her asking her to perform abortion and inquiring her fee, as if it were the most natural thing in the world The open, bare-faced trade in abortifacients was enormous and scandalous and there was no legal redress She knew women who had used abortifacient pills every month of their lives This matter was not touched by the medical profession at all The medical profession refused to perform abortion, and women went to these sharks and the law could not touch them

Dr BERESFORD KINGSFORD maintained that the production of an abortion with the consent of the woman wronged no one. He agreed that the woman should be mistress of the situation The only ground on which the procuring of abortion could be held to be a crime was that it deprived the community of a possible citizen, that the Empire had many enemies and needed more children to speak with the enemy in the gate In his opinion we were getting more children than we needed, in peace we had many more than we could employ, and the Great War had taught us not to rely on the C 3 population of this island but on the united voluntary efforts of the King's Dominions throughout the world Contraception was depriving the community of far more citizens than those practitioners who worked up side-streets producing perhaps a hundred abortions, the sale of contraceptive appliances had deprived the country of tens of thousands Yet books on the subject were on every bookstall, and a great political party was bringing forward instruction in conception control as a plank in its platform A woman might be subjected to very unfair pressure by a lover or husband, and what he would insist on was that no woman should be forced to undergo the operation without her consent and until she had been informed of the risks involved

Sir BERNARD SPILSBURY said that the scientific facts could not be regarded as doubtful, the individual was alive from the moment of conception The fact of birth was a mere incident in his life The only sanction for destroying one life would be that it would endanger another or very seriously prejudice the health of the mother Borderline cases must be very difficult to decide on, yet there was the guidance that morally the operation would be murder unless there was some justification in the life of the mother. He agreed that abortion was exceedingly rife, the cases that came to court represented only a very small proportion of those occurring and there was no doubt that the proportion was much smaller than it was 20 years ago Since the war it had increased considerably, and the view of the public had undergone a change

Prof A. DONALD said that, as it happened, the legal and medical aspect coincided He agreed with Dr Fairbairn that the line must be drawn somewhere, and at the purely medical indications that he had mentioned If not, he did not see why the profession should not fall into the extreme attitude that it was merely a question for the woman concerned He had a great admiration for the sex, but in this matter women had no morals whatever, they quite expected *the doctor to pass a sound whenever they had not* been unwell for two or three days Many of the abstract difficulties did not arise in real practice. He had induced many abortions, four-fifths of them for hyperemesis, but he had never failed to convince a woman that it was her duty to go on with her pregnancy in the cases where there was no medical indication The profession still adhered to the line laid down as a tradition for all these years, it would be a great mistake if they once began to depart from it

Summing-up

Lord Justice SALTER, summing up the discussion, said that he looked at the question with the eyes of a lawyer, and viewed in this precise manner, the practical problem appeared to be What is and what ought to be law in this country with regard to the artificial procuring of abortion ?" Every doctor desired that the law should be so framed that his duties as a citizen should never conflict with his duties to his profession Dr Taylor in his "Medical Jurisprudence," headed one section 'Justifiable Abortion," and this section was still retained in the latest edition It began by saying that there was no abortion that was justifiable in law Dr Taylor's view seemed to be that the term "unlawful use of drugs &c was merely a term of abuse, but in his (Lord Salter's) opinion the fact of forbidding unlawful use implied that there was a lawful use A very difficult case might arise if it were found during the pregnancy that one or other parent were suffering from a disease usually inherited He thought the mother should have more say than anybody else but it was going rather far to say that to effect abortion should be lawful in any case where the mother desired it Here was a living thing alive in the mother, in many senses existent already Was her right to cease at the moment of birth ? Had she not an equal right to kill it after it was born ? It was the view of masses of human beings in ancient times that parents had that right He could not see a logical distinction between the parent's right to abort a fœtus and the right to expose the child He had been impressed by Prof McIlroy's phrase that any abortion was homicide If abortion *were ever* sanctioned outside the strictly medical area for economic or social reasons, he would have great fears Even where it was restrained within the medical area, he would fear the growth of a large class of compliant doctors who would be easily persuaded that there were sufficient medical reasons, their presence would be all to the advantage of the rich Some speakers had boggled at the idea of *many* abortions by the same doctor on the same woman, but if the operation was morally justified in a given set of circumstances it was obvious that it was equally justified another time He was quite sure that those who proposed to extend the sanctions for abortion outside purely medical limits would find themselves up against an enormous body of instinctive but very powerful public opinion The early Christian Church had found abortion regarded in the Roman world much as social excess was regarded by our immediate ancestors—undesirable but so common as to call for no great censure The attitude of the infant Church had been most uncompromising and had never since wavered That view, deep down in the hearts of people, would rise up and have enormous force if it were ever proposed to extend the liberty of abortion

---

A report of the Discussion on the Treatment of Chronic Non-tuberculous Infection of the Lungs at the meeting of the Combined Sections of Medicine Surgery and Laryngology of the Royal Society of Medicine will be found on p 262

SOCIETY OF MEDICAL OFFICERS OF HEALTH

A MEETING of this Society was held on Jan 21st, Dr E H SNELL the President, in the chair. Dr S MONCKTON COPEMAN, F.R S, from the point of view of the Government department, opened a discussion on

EDUCATION OF THE PUBLIC IN THE PREVENTION OF DISEASE

It had been suggested, he said that the Ministry of Health ought to give more of a lead to the adoption of new methods of prophylaxis against infectious disease. A government however could not usefully take special action in advance of public opinion and its policy was to provide the minimum of direct propaganda while doing all it could to encourage public authorities and voluntary agents to so educate the people that new methods would have a chance of succeeding The Medical Department of the Ministry issued monthly bulletins with abstracts of important foreign literature, and the Publicity Department issued periodical statements to the press. Summaries of knowledge to date were also issued from time to time Much of this output from the Ministry could be regarded as propaganda of considerable interest and importance A good instance of the Ministry's efforts to forward the use of beneficial methods was its action in setting out the Schick method of protection against diphtheria It had responded to numerous requests for assistance from medical officers of health and of public and private schools and much help had been given by the Wellcome Laboratories The Schick test, followed by immunisation of susceptible persons had been carried out on 6000 children and adults none of whom had since contracted diphtheria, though many had been in contact with cases of it It was of great importance to immunise all children at pre-school age so as to avoid the risk of contracting the disease on entering school life but so far this had been attempted only on a very small scale: pioneer work of this kind had been done by Dr. C W Hutt, medical officer of health for Holborn The Ministry was now considering the question of more direct propaganda by means of local conferences which would be attended by members of the staff of its medical department This department should be looked upon as a central bureau of information engaged in investigating and recording epidemiological, statistical and laboratory work in this country and abroad concerning the prevention of infectious disease and supervising the technical work involved in the production of immunity

The Press

Lord RIDDELL said that it was evident from Dr Copeman's remarks that the *Government* was not disposed to take the initiative in educating the public on these matters, its object being, apparently, to get somebody else to do this educating He thought that the press as a whole could not be charged with any disinclination to deal with medical matters If some gigantic scheme of preventive inoculation was contemplated, the Ministry of Health should first formulate its proposals discussion of which by Parliament would focus public attention on them No doubt the services of experts would be available to explain the scheme If medical officers of health supplied the press with interesting copy on vital subjects they could be sure of having what newspaper people called a double top ' The measures involved in the prevention of infectious disease were serious, they implied complete confidence in the efficacy of certain treatment, they meant an interference with the liberty of the individual, and propaganda in their favour might start an agitation against them. Vaccination against small-pox had been of great benefit to the community, but just because it had been made compulsory and some measure of attention had been drawn to it, much opposition to it had been aroused. What was likely to be the reception of a proposal to inoculate all young children? Was the profession as a whole in favour of such preventive measures? He thought it unlikely that the press would try to form public opinion on this matter, but probably the papers would open their columns to a discussion of the subject, provided it was carried on by persons with due qualifications and that they did not fix their remuneration at too high a figure.

The Medical Officer of Health

Dr. C W **HUTT** said that he would favour general immunisation against tuberculosis, enteric, and other diseases. The problem at present centred chiefly around small-pox and diphtheria. He was a firm advocate of personal persuasion in the attempt to gain public sympathy for prophylactic measures. It was encouraging to find Camberwell and Westminster taking up the Schick test for diphtheria. The opposition of the Anti-vaccination League had always to be reckoned with, sometimes the statements issued by that body were grossly wrong. He thought that cinematograph films and wireless could well be brought into the campaign, though admittedly the most powerful agency was the press, especially as, even now, many people felt that if anything appeared in print it must be true.

The Standpoint of the Public.

DEAN INGE, referring to attempts made in the first weeks of the late war to prevent the inoculation of British troops against typhoid, said that in the Boer War there had been between 16,000 and 17,000 deaths from this disease in an army of 200,000. It was not too much to say that if the anti-vaccinist crusade had succeeded in 1914 we should have lost the war. The ignorance of the public remained astounding, though not so bad as 50 years ago. He had only one additional suggestion to make—namely, that the churches should set apart one Sunday in the year—perhaps St Luke's Day—as Health Sunday. On that day the pulpits might be occupied by medical officers of health. The main responsibility in this matter, however, rested with the doctors themselves. In the past they had been too timid, too afraid of medical etiquette, and of public opinion, they had not shown quite the courage they ought to have done. They certainly had been slow in enlightening the public about the nature of certain contagious diseases which were even more serious than small-pox. And he thought the profession might well tell the public a little about the well-established laws of heredity, that it was not good for epileptics or deaf-mutes to marry. Medical men were listened to very patiently and respectfully. The modern man might doubt whether he had a soul, he might forget that he had a mind, but he was acutely aware that he had a body.

The Point of View of the Laboratory Director

Prof J C **LEDINGHAM**, F R S, said that the best advertisement which could be given to a product of research was the assurance that it rested on a solid scientific foundation, that it had no secret corners, and that it had been tested as far as possible on animals, or, as in some instances, on human volunteers. It should then commend itself to the public without the need of any special propaganda. But the public must not try to force the researcher's hands. The value of diphtheria antitoxin had been tested up to the hilt before it was used on patients. The story of tuberculin showed how even a great figure-head could go astray. Koch himself had laid down the conditions which specific therapy should fulfil, but not until his third paper did he state what his substance was, feeling, he said, that physicians would be less prejudiced if they did not know. This illustrated the necessity for the investigator to stick to the rules of the game, however distinguished he might be. Public health would benefit, he thought, if measures were taken on suspicion of an attack of disease, without waiting for definite symptoms to develop. In this country we had been slow to adopt prophylactic measures. In his view, the chief need in propaganda was to have an informed public press. At present it served out from sheer ignorance, what was a mere burlesque of the facts. The burden of the work could well be borne by the various welfare organisations and institutions. After all, vaccination was cheaper than small-pox, and the widespread reduction of incidence following widely used immunisation would be a gain cheaply acquired.

Dr C S **THOMSON** contended that the working man was very amenable to persuasion in these matters. The general practitioner dare not write an article to the press on health subjects, for fear of having his name removed from the Register. Medical officers had already appeared in the pulpit. He thought that films might also be made and shown.

CHELSEA CLINICAL SOCIETY

AT a meeting of this Society held on Jan 8th Dr J D **ROLLESTON**, Vice-President, opened a discussion on the practical results of

Recent Researches in Acute Infectious Diseases

The diseases, he said, in which the most useful results had been obtained from recent research were in order of importance, diphtheria, measles, scarlet fever, and typhus, and these results could be ranged under the headings of diagnosis, prophylaxis, and treatment. As regards diagnosis, the most important discovery in recent years was the Weil-Felix test which occupied as important a position in the diagnosis of typhus fever as the Wassermann reaction in the diagnosis of syphilis. Although the causal agent of scarlet fever was probably a variety of hæmolytic streptococcus and that of measles a green-producing diplococcus, bacteriological methods were not at present available for the clinical diagnosis of these diseases. Personally Dr Rolleston had not found that recent tests had given him any assistance in the diagnosis of scarlet fever, but he admitted that several observers both at home and abroad were inclined to attach considerable diagnostic significance to the Dick test and Schultz-Charlton reactions. From the practical standpoint the most useful results came under the heading of prophylaxis especially as regards diphtheria, measles, and scarlet fever in the order named. Dr Rolleston gave a brief description of the Schick test, active immunisation against diphtheria by toxin-antitoxin, the serum prophylaxis of measles, and immunisation against scarlet fever. In dealing with treatment he remarked that investigation had shown that there were no grounds for regarding alcohol as a cardiac stimulant. The most that could be said for it therapeutically was that it acted as a narcotic and that in adults accustomed to its use it produced a sense of euphoria. In treating children, who formed the great majority of patients suffering from acute infectious diseases there appeared to be no justification for its use.

The most remarkable result of recent research, continued Dr Rolleston, was the application of serum therapy to scarlet fever. His own experience had been limited consisting merely of about 50 cases, for, unlike some enthusiasts, he did not think it necessary to use scarlet fever antitoxin as a routine measure, but reserved it for severe cases. The best results were obtained by the use of a concentrated serum whereby the frequency and severity of serum sickness was reduced to a minimum, while the tendency to faucial ulceration was apparently checked and a striking improvement in the general condition resulted

Reviews and Notices of Books.

CLINICAL METHODS

Finlayson's Clinical Manual Fourth edition Edited by CARL H BROWNING, M D, E. P. CATHCART, M.D. F R S and LEONARD FINDLAY M D D Sc. Revised and augmented by various contributors London: G Bell and Sons Ltd 1926 Pp. 815 18s

Examination of the Patient and Symptomatic Diagnosis By JOHN WATTS MURRAY, M.D. London · Henry Kimpton. 1926 Pp 841 36s

History Taking and Recording By JAMES A. CORSCADEN M D. Associate in Obstetrics and Gynecology, Columbia University New York. New York · Paul B Hoeber Inc. 1926 Pp 78 $1.50

THE great increase in bacteriological and chemical aids to diagnosis during this century brings with it a grave danger that students may come to regard diagnosis as a mechanical science, losing sight of the fact that more frequently it is a philosophic art. The reissue of Dr Finlayson's well-known Clinical Manual for the Study of Medical Cases ' after a lapse of 35 years is thus very welcome the editors have chosen coöperators admirably, and have produced a book which contains much of the *spirit* of the original. Certain portions, indeed, have been retained almost in their entirety, and the late Sir William Gairdner's contribution on the physiognomy of disease is reproduced in its classical form. The only section which is completely new is that by Dr E P. Cathcart on disease of the glands of internal secretion, this is a very well-written, restrained contribution, in excellent keeping with the rest of the book. Laboratory tests are not omitted, but those described are for the most part such as can be carried out in ward side-rooms On the other hand, since a most important duty of the student is to obtain specimens for examination, emphasis has been laid throughout on the precautions to be observed in furnishing such specimens. The section on examination and reporting of medical cases has been well revised by Dr Leonard Findlay · a general scheme is followed by a discussion on the various parts of the "history.' From the point of view of the student, for whom the book is primarily intended, it is perhaps rather long, but it is very readable and is altogether a worthy product of the Glasgow school.

The 800 large pages of Dr Murray's book are concerned only with what he describes as an ' outline for history taking" In a preliminary section he describes a general scheme for eliciting a "history and for the examination of the patient, and then goes on to deal in more detail in a second part with diseases of single organs or of systems of the body He rightly holds that "every first-class diagnosis must be preceded by a thorough history," but a history of such detail and minuteness as Dr. Murray appears to require would seem to be so laborious an undertaking that diagnosis and treatment could hardly be efficiently carried out by the exhausted historian It is stated that the subject matter is gathered from standard works but some curious questions are hardly made clearer by the appended notes. For example, in dealing with diseases of the circulatory system Dr Murray puts the question ' Does the heart skip a beat at intervals of one-half to one and a half minutes? Is the patient in perfect health?" followed by the explanatory note Arrhythmia It may occur in healthy persons ' This is surely too vague. Again the patient is asked, with reference to the liver if he has suffered from diabetes or rickets The reason for this question is given as "look for atrophic cirrhosis. Questions with explanatory comments form the bulk of the book, and vague or inaccurate ones, though only rare in comparison with the immense number in the volume, do detract somewhat from its value. Illustrations are profuse and those in the section on the ductless glands are an excellent collection.

Dr. Corscaden's little book deals briefly with the art of history taking and recording, and while the volume suffers slightly from the fact that the specialty of the author is given too prominent a place it is quite a useful production The discussion of difficult problems in history taking and the devices set out for handling difficult patients are valuable, while the author's differentiation of the two arts—that of eliciting a complete history and that of recording it clearly—will serve to impress the student with the need for taking pains in his work.

PRACTICAL SURGERY OF THE JOSEPH PRICE HOSPITAL.

By JAMES WILLIAM KENNEDY, M D., F.A.C S, Surgeon to the Joseph Price Hospital, Philadelphia Philadelphia. F. A. Davis and Co 1926 Pp 861. $10.

Dr Joseph Price was a surgeon of Philadelphia of great personality who died in 1911. There is no doubt that he was a great teacher, a skilled technician, and a forceful character Dr. James Kennedy was his assistant for 11 years, and was so impressed with the work of his chief that 15 years later he has felt impelled to write a book extolling Dr Price's methods on almost every page For him Joseph Price could do no wrong Time after time the author declares his master to have written the last word on the particular subject he is discussing The book is thus full of sentiment, but in spite of this it contains good material Much of its teaching is provocative, but the obvious sincerity of the author persuades us that, although he may over-rate the virtues of the methods of his late chief there is nearly always in them a sound basis which may not be disregarded. Like many enthusiasts he ascribes views to his opponents, in this case the physiological surgeons," which they do not hold, and then sets out to show how wrong these views are One of his most strongly held tenets is the extraordinary resistance which the inflamed peritoneum offers to manipulation In acute appendicitis he is a strong upholder of freeing all bowel which has formed adhesions. He believes that this eliminates subsequent obstruction and that it is perfectly safe, for absorption of toxic material by the inflamed peritoneum is reduced to a minimum. He believes that it is safe to break down adhesions, even in tuberculous peritonitis, where careful and systematic separation of all adherent coils of bowel is recommended.

The author is a strenuous advocate of carrying out drainage in the inflamed abdomen by means of a gauze pack, but curiously enough, in the section on treatment of the inflamed gall-bladder, we find that his gauze is surrounded by oil-silk to prevent adhesions from taking place between the duodenum and the gall-bladder When discussing cervical erosions Dr. Kennedy stresses the extreme importance of this pathological condition, since he believes it to affect strongly the mentality and general comfort of the patient For a much injured cervix he recommends vaginal hysterectomy.

There are interesting observations scattered through the book For instance, it is declared that if one ovary has been removed because of cystic disease the other ovary is very liable to become cystic if the uterus remains but not if the uterus is removed. In fact, it is said that with the uterus remaining 90 per cent. of such cases return for a second operation on the opposite ovary Again, on page 460, the author declares that the removal of a tuberculous kidney causes a subsidence of a tuberculous lesion beginning in the other kidney In the treatment of carcinoma of the breast the author does not advocate removal of the pectoral muscles since he says that Dr Price pointed out that this procedure did not add to the thoroughness of the removal of the malignancy nor to the prevention of its recurrence. Such a view, although unorthodox, is worth consideration In his practice catgut seems never to be used even in septic cases and neither are gloves We cannot agree with the contention that gloves hamper the work of the intra-abdominal surgeon It is a question of training and the development of sensitiveness of the finger-tips The book is interesting because it illustrates Mr G K Chesterton's contention that the Americans are a foreign nation, it is valuable because it throws doubt on some well-established methods of the present day

DISEASES OF THE EAR

Handbuch der Hals-Nasen-Ohren-Heilkunde Edited by A DENKER and O KAHLER Vol VII *Diseases of the Ear* Part 2 Berlin Julius Springer Munich J F Bergmann, 1926 Pp 804 R M 72

THE seventh volume of Denker and Kahler's great handbook forms the second of the three devoted to diseases of the ear It deals entirely with pathology and treatment, and is subdivided into sections on the external ear, middle ear, inner ear, tuberculosis, syphilis, and tumours, including a chapter on tumours of the acoustic nerve This volume, therefore, includes the greater part of the description of ear diseases from the clinical aspect; intracranial complications of ear disease will be discussed in the next volume, together with the subject of deaf-mutism, while methods of examination and testing, as well as general ætiology, have been dealt with in the preceding one The whole subject of non-suppurative middle-ear deafness, apart from otosclerosis, is discussed by A Scheibe under the heading of "Diseases of the Eustachian Tube—Closure of the Tube," and occupies but 18 pages, a much less complete account of an important subject than would be expected in a work of this size and scope As to treatment, the author prefers the Politzer method and rarely employs the Eustachian catheter, the use of which is but very briefly described; treatment with bougies is only mentioned in the statement that the author has no experience of their use With this exception the work is fully up to the very high standard set by the volumes previously published

There is a copious index of subject matter and another of authorities; a list of references to literature follows each chapter, and a full paged table of contents is included at the beginning of the book, these features add much to its value as a work of reference

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol XXIII October–December —In their paper entitled Investigation of a Case of Henoch's Purpura treated by Splenectomy, Dr Bernard Myers, Dr A Knyvett Gordon, and Mr Rodney Maingot record a case of severe Henoch's purpura in a girl of 6, which had existed for a year During the last ten months of this period continuous bleeding from the kidneys had undermined her strength and a fatal issue seemed imminent All medical treatment failed to stop the hæmaturia Splenectomy, however, was followed by cessation of hæmaturia and improvement in general health Two months after operation the patient seemed to be a normal child, and there had been no recurrence of hæmaturia Pathologically the case is remarkable as being the first example of Henoch's purpura on record in which phagocytic giant cells are described The histological appearances of the excised spleen are illustrated in a coloured plate —In the second part of their paper on Epiloia, Dr T Brushfield and Dr W Wyatt deal with the pathology of the disease They point out that the condition in the brain is one of hypertrophic nodular sclerosis or tuberose sclerosis, which is a congenital lesion characterised by marked hyperplasia of the neuroglia elements which gives rise to tumour-like masses in various parts of the brain Microscopically the condition is a gliosis in connexion with which peculiar giant cells or ganglion cells are observed — Dr Brushfield and Dr Wyatt also contribute a paper on Microcephalic Children, based on observations at the Fountain Mental Hospital They state that the diagnosis of true microcephaly rests on three distinguishing and never-varying features (1) cranial measurements all below normal, (2) fronto-parietal recession with occipital flattening and (3) dwarfism Accessory features are (4) early closure of the anterior fontanelle and all sutures, (5) a pointed ridged vertex, the ridge in marked cases extending down the frontal bone to the glabella, and (6) recession of chin and prominent nose All grades of mental deficiency occur in association with microcephaly, but most of the writers' cases belonged to the low-grade imbecile and idiot groups Both the papers are illustrated by excellent photographs showing the naked-eye and microscopical appearances of the brain in epiloia and the characteristic features of microcephalic children —Dr E C Willcox reports a case of Concurrent Varicella and Herpes Zoster The patient was a boy aged 4 years in whom a characteristic eruption of herpes zoster on the left side of the chest was followed, four days later, by a generalised eruption of varicella, the lesions of which were scattered over the trunk, face, and scalp, and were also present on the palate, base of the uvula, and buccal mucous membrane Both eruptions were extremely characteristic, and both developed and terminated in the manner commonly seen in the two diseases Comments on the case, with a review of the literature, are appended by Dr J D. Rolleston — The abstracts from current literature are devoted to dermatology and syphilis.

BRITISH JOURNAL OF OPHTHALMOLOGY December 1926 —Wajid Ali Khan discusses the Pathogenesis of Microphthalmos, his material being derived from two human and two pig's microphthalmic eyes He attributes the abnormality not to intra-uterine inflammation, as has been suggested, but to an arrest of normal development In this connexion he thinks that fright may be an operative cause One of the cases was that of a child of an unmarried mother, and he suggests that the shock to the nervous system of the mother on first realising her condition about the time when the primary optic vesicles of the fœtus were being formed was the effective cause The suggestion appears to be somewhat fanciful —L G Dodds records an instance of congenital defect of abduction of one eye associated with retraction of the eyeball in adduction Jameson Evans, who recorded one of these cases in 1903,[1] favoured the view that the external rectus in these cases is wholly or partially converted into a fibrous band There may also be a faulty insertion of the muscles Each case must be investigated separately as the appropriate treatment may not be the same for all ——January, 1927 · Crater-like Hole and Coloboma of the Disc associated with Changes at the Macula, by K T A Habertsma, of Delft, Holland The case (illustrated by a coloured plate and charts) differs from the more ordinary cases of "hole" in the disc, in that the vision of the eye was seriously affected by a large scotoma including the macula Presumably the "hole" was caused by an absence of the papillomacular fibres The author suggests an abnormal growth of the retina protruding into this portion of the disc —Bitemporal Contraction of the Visual Field in Pregnancy, by I Ambramowicz, of Vilna The author has reinvestigated this subject, which was brought before the International Congress of Ophthalmology at Washington in 1922, by C E Finlay and Maud Carvill, who found that a large proportion of normal women showed the phenomenon in the later months of pregnancy, they attributed it to enlargement of the pituitary gland Isolated cases have been observed, by J Herbert Fisher[2] and many others The conclusion of Ambramowicz, based on the examination of 81 normal women in the last month of pregnancy, is that the phenomenon cannot be demonstrated in more than about 6 per cent of pregnant women An excellent account of the relations of the pituitary body to vision is to be found in Prof de Schweinitz's Bowman lecture published in the Transactions of the Ophthalmological Society for 1923

THE LANCET.

ONDON. SATURDAY, JANUARY 29, 1927.

BORTION LAWFUL AND UNLAWFUL

ECENT discussions have revealed the uncertainty e medical profession as to how far the law permits termination of pregnancies The legal aspect, a speaker at the British Medical Association ing last July, is that induction of abortion is ys against the interests of the State, it is a nal offence, and legislative measures and precau- have been taken to prevent its performance ot in cases of medical necessity That statement e, but it does not appear upon the face of the ces Against the Person Act of 1861—the enact- usually employed in prosecuting abortionists iosoever,' says Section 58 of that Act, "with t to procure the miscarriage of any woman, her she be or be not with child, shall unlawfully nister to her any poison or other noxious ;, or shall unlawfully use any instrument or other ns whatsoever with the like intent, shall be guilty felony, and, being convicted thereof, shall be le to be kept in penal servitude for life" Except the addition "whether she be or be not with child," se words are 90 years old, for the 1861 Act borrowed m from an Act of 1837 Perhaps if they were enacted again to-day an express proviso would inserted to exempt from criminal liability the y qualified practitioner who terminates a pregnancy the bona fide purpose of preserving the mother n special danger to life or health But, as it stands, law contains no such saving clause, its language ormidable and uncompromising How comes it, n, that such operations are ever otherwise than minal? The answer lies in that word "unlawfully," ich creates the implication that abortion may be rful as well as unlawful

awfulness or unlawfulness may ultimately be a estion for judge and jury But no conviction l follow if the practitioner has acted on bona fide dical grounds, and if no conviction is likely prosecution will be undertaken As, however, practitioner has no express statutory exemption m criminal liability, he may be called upon to ablish his bona fides, therefore, he is well-advised emember that, in Lord RIDDELL's phrase, "secrecy he badge of fraud," to explain to the woman her friends the course he proposes to take, to obtain the confirmation of a second opinion statutory provision of 1861 already quoted is not, ourse, the whole of the law The same section es it felony for a pregnant woman to attempt rocure her own miscarriage, and a succeeding *on makes it a misdemeanour for anyone to supply rocure any poison, instrument, or other means, ving it to be intended for the unlawful procuring niscarriage Quite apart from statutes, to procure abortion of a quick child is stated by COKE others to be a misdemeanour at common law, over, the law of conspiracy has often been 'ssfully invoked to secure the joint conviction woman and her assistants in abortion There is ther issue where an unlawful attempt to procure rriage results in death At one time the judges ded this as clear murder, and visited it with eath sentence Later, the Home Office so frequently commuted the capital sentence, and juries were found so reluctant to convict of this kind of "constructive" murder, that the judges changed their practice They began to tell juries that they *might convict of mere manslaughter unless they* thought the accused must have—or ought to have—contemplated that death or grievous bodily harm was likely to result Here our English law was mitigating its rigours against unlawful abortion, and perhaps unwisely, for the change placed the practised abortionist in a better position than the mere first offender But that is the limit of legal tenderness The offence is difficult to prove, for witnesses are seldom present, the law, therefore, has enlarged the evidence admissible To throw light on the lawfulness or unlawfulness of an operation, to prove the intent with which the noxious thing was administered or the instrument used, the courts have admitted evidence showing that the accused has on previous occasions used similar means with the avowed intent to procure abortion, or that he or she has previously admitted having done the same thing to other women Such evidence of previous incidents—which normally the judges are alert to exclude—was held admissible in an abortion charge in 1906, because it authorised a reasonable inference of systematic conduct In 1922 the courts went further With the subsequent confirmation of the Court of Criminal Appeal, evidence that a doctor administered drugs to one woman with intent to procure abortion was held admissible in support of a charge of having used an instrument upon another woman for the same intent, and vice versa—not to prove thereby that the defendant used the instrument or administered the drug, but to rebut the contention that he did so innocently In 1909 the evidence of a woman employed as a police spy to entrap the accused (and, therefore, alleged by the defence to have instigated the crime) was accepted, and corroboration was held unnecessary Punishment is substantial Lord READING, when Lord Chief Justice in 1916, was asked to reduce a sentence of three years penal servitude upon a convicted abortionist He refused on the ground that it was an offence for which a severe sentence was the only sentence possible "The courts must mark their view of these offences which do not become less frequent as time progresses and may not tend to be less frequent in the future" It will be seen that, in Lord RIDDELL's words, abortion is a risky game When many of these decisions were given, a fully qualified medical practitioner was standing in the dock

The member of an honourable profession who, honestly using his best skill and judgment, acts solely in the medical interests of his patient, is in no danger of prosecution or penal servitude His guiding principle is clear, and if its application is difficult in a particular case, it is the kind of difficulty daily encountered in medical practice, as Earl RUSSELL put it during a recent discussion, the removal of a fœtus is as much a medical question as the removal of a tumour The practitioner must disregard everything except the medical aspect of the case He is not to be persuaded by vague and unexamined pleas of feared ill-health, nor to give way to those who would evade the ordinary inconveniences, discomforts, and risks of child-bearing He is not to degrade his calling or abrogate his judgment by shirking the duty of refusal on the ground that, if he refuses, some other practitioner may be found more pliant He is not to regard the economic consequences nor —with one possible exception—*the social consequences* of childbirth, these considerations will afford him no legal defence The one possible exception of sensitiveness of the finger-tips The book is interesting because it illustrates Mr G K Chesterton's contention that the Americans are a foreign nation, it is valuable because it throws doubt on some well-established methods of the present day

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol XXIII October–December —In their paper entitled Investigation of a Case of Henoch's Purpura treated by Splenectomy, Dr Bernard Myers, Dr A Knyvett Gordon, and Mr Rodney Maingot record a case of severe Henoch's purpura in a girl of 6, which had existed for a year During the last ten months of this period continuous bleeding from the kidneys had undermined her strength and a fatal issue seemed imminent All medical treatment failed to stop the hæmaturia Splenectomy, however, was followed by cessation of hæmaturia and improvement in general health Two months after operation the patient seemed to be a normal child, and there had been no recurrence of hæmaturia Pathologically the case is remarkable as being the first example of Henoch's purpura on record in which phagocytic giant cells are described The histological appearances of the excised spleen are illustrated in a coloured plate —In the second part of their paper on Epiloia, Dr T Brushfield and Dr W Wyatt deal with the pathology of the disease They point out that the condition in the brain is one of hypertrophic nodular sclerosis or tuberose sclerosis, which is a congenital lesion characterised by marked hyperplasia of the neuroglia elements which gives rise to tumour-like masses in various parts of the brain Microscopically the condition is a gliosis in connexion with which peculiar giant cells or ganglion cells are observed —Dr Brushfield and Dr Wyatt also contribute a paper on Microcephalic Children, based on observations at the Fountain Mental Hospital They state that the diagnosis of true microcephaly rests on three distinguishing and never-varying features (1) cranial measurements all below normal, (2) fronto-parietal recession with occipital flattening and (3) dwarfism Accessory features are (4) early closure of the anterior fontanelle and all sutures, (5) a pointed ridged vertex, the ridge in marked cases extending down the frontal bone to the glabella, and (6) recession of chin and prominent nose All grades of mental deficiency occur in association with microcephaly, but most of the writers' cases belonged to the low-grade imbecile and idiot groups Both the papers are illustrated by excellent photographs showing the naked-eye and microscopical appearances of the brain in epiloia and the characteristic features of microcephalic children —Dr E C Willcox reports a case of Concurrent Varicella and Herpes Zoster The patient was a boy aged 4 years, in whom a characteristic eruption of herpes zoster on the left side of the chest was followed, four days later, by a generalised eruption of varicella, the lesions of which were scattered over the trunk, face, and scalp, and were also present on the palate, base of the uvula, and buccal mucous membrane Both eruptions were extremely characteristic, and both developed and terminated in the manner commonly seen in the two diseases Comments on the case, with a review of the literature, are appended by Dr J D Rolleston —The abstracts from current literature are devoted to dermatology and syphilis

BRITISH JOURNAL OF OPHTHALMOLOGY December 1926 —Wajid Ali Khan discusses the Pathogenesis of Microphthalmos, his material being derived from two human and two pig's microphthalmic eyes He attributes the abnormality not to intra-uterine inflammation, as has been suggested, but to an arrest of normal development In this connexion he thinks that fright may be an operative cause One of the cases was that of a child of an unmarried mother, and he suggests that the shock to the nervous system of the mother on first realising her condition about the time when the primary optic vesicles of the fœtus were being formed was the effective cause The suggestion appears to be somewhat fanciful —L G Dodds records an instance of congenital defect of abduction of one eye associated with retraction of the eyeball in adduction Jameson Evans, who recorded one of these cases in 1903,[1] favoured the view that the external rectus in these cases is wholly or partially converted into a fibrous band There may also be a faulty insertion of the muscles Each case must be investigated separately as the appropriate treatment may not be the same for all ——January, 1927 Crater-like Hole and Coloboma of the Disc associated with Changes at the Macula, by K T A Habertsma, of Delft, Holland The case (illustrated by a coloured plate and charts) differs from the more ordinary cases of " hole " in the disc, in that the vision of the eye was seriously affected by a large scotoma including the macula Presumably the " hole " was caused by an absence of the papillomacular fibres The author suggests an abnormal growth of the retina protruding into this portion of the disc —Bitemporal Contraction of the Visual Field in Pregnancy, by I Ambramowicz, of Vilna The author has reinvestigated this subject, which was brought before the International Congress of Ophthalmology at Washington in 1922, by C E Finlay and Maud Carvill, who found that a large proportion of normal women showed the phenomenon in the later months of pregnancy, they attributed it to enlargement of the pituitary gland Isolated cases have been observed, by J Herbert Fisher[2] and many others The conclusion of Ambramowicz based on the examination of 81 normal women in the last month of pregnancy, is that the phenomenon cannot be demonstrated in more than about 6 per cent of pregnant women An excellent account of the relations of the pituitary body to vision is to be found in Prof de Schweinitz's Bowman lecture published in the Transactions of the Ophthalmological Society for 1923 the plan "in the present state of public feeling," and remarks that "the suggestion might be more convincing if supported by the results of extensive experience" It appears, however, that only by modifying the virus or the dosage employed in vaccination are we likely to secure assent for the universal protection of infants, and Dr KINLOCH's method, if effective, would so disarm public hostility as to make general vaccination once again practical politics The next, or third, alternative is to abandon universal vaccination altogether in favour of the effective treatment of contacts in the face of an epidemic Present experience in Sheffield goes to show that under a sufficient stimulus the majority of people in an infected area will present themselves for protection, whether contacts or not, but it is likely that even if compulsory vaccination of infants were sacrificed, Parliament would still be unwilling to give power to the Ministry of Health to make vaccination compulsory within "an infected area" Criticism might be lessened, however, if such vaccination aimed at conferring only brief and temporary immunity, and it is theoretically possible to check the progress of an epidemic by using an antigen producing symptoms so far negligible that popular prejudice would soon fade away Nor should it be necessary to give the whole of a threatened population this transient protection Indeed, if they were forced to receive it during one epidemic, they would have a legitimate grievance when a year or two later the public health authorities demanded that they should be vaccinated again The measure would be reserved for contacts only For them, however, it must be compulsory to be effective It may be that we have not yet achieved sufficient accuracy in vaccine standardisation or in measuring individual response to enable us to estimate either the dose or the probable amount and duration of any immunity which might thus be conferred These are matters into which the Departmental Committee now sitting is quite competent to inquire

THE PROBLEM OF INFECTIVE ENDOCARDITIS

TWO years ago a Research Fund was initiated,[1] in memory of the late Mr R L St J HARMSWORTH, for the investigation of the problem of ulcerative endocarditis, and a Scientific Committee, consisting of Sir THOMAS HORDER, Sir THOMAS LEWIS, Sir COOPER PERRY, and Dr MERVYN GORDON, was appointed to advise the trustees on the administration of a fund which now exceeds £25,000 in amount On the advice of this committee grants will be made to individual workers in Great Britain or elsewhere on account of contributions to chemical or other research, and the Trust deed contains a provision to the effect that the whole of the capital remaining at any time may be granted to the author of a contribution which is judged to have finally disposed of the present obscurity overlying our knowledge of infective endocarditis, and to have given the medical profession control over the disease Although in many respects knowledge of infective endocarditis in its more intimate details lingers somewhat, it is clear that clinical recognition of the condition has been much commoner in recent years that it was at the beginning of the century At that time it was something of a curiosity, but, as is the case with so many disorders, once attention was directed towards it, evidence was soon obtained that it was of much more frequent occurrence than had been supposed This is particularly true of the subacute form Published accounts of the disease indicate a greater frequency in some parts of the world than others, but this needs confirmation Moreover, clinicians with long experience of cardiac disease have the impression that since the war period there has been a definite increase in the number of cases Trustworthy evidence on this point is, however, difficult to obtain Despite the increase and greater dissemination of knowledge of the varied clinical appearances, hospital experience suggests that a diagnosis of the condition is usually made only some considerable time after its inception The insidious nature of its onset is a partial explanation of this and the result of it is that little is known of the very early stages of the condition, the time at which the source of the infecting agent might presumably be sought with the greatest hope of success Much information might be gathered by study of the bacteriology of the blood stream in the course of unexplained febrile conditions occurring in patients suffering from cardiac disease In earlier times the isolation of organisms from the blood was considered a sine qua non in making a diagnosis Now it is becoming increasingly clear that in many cases this cannot be done Considerations of technique do not explain the failures recorded There are cases in which the clinical diagnosis is unmistakable, in which the post-mortem findings are typical, but which at no time during the period of observation reveal evidence of bacteriæmia The transition from one stage to the other has been observed in a few instances but much more information upon this phase of the disease is required. The prognosis is always extremely bad but evidence is gradually accumulating to show that recoveries do occasionally occur Specimens are from time to time seen which suggest very strongly that there has been a bacterial infection of the valves at some time or other which has completely healed, leaving a damaged valve It is quite possible that the cases usually seen are merely a special selection of bad infections There may be much milder cases which recover without going on to this serious disorder This is suggested by certain recorded observations, but can only be settled by further work on the bacteriology of the blood in febrile conditions

The acute fulminating infections are usually due to one of the pyogenic organisms But the distinction between acute and subacute is in this connexion quite arbitrary, and it would not be surprising to find a case of the latter variety due to one of the more highly pathogenic organisms A few cases of subacute endocarditis are caused by Pfeiffer's influenza bacillus but the great majority (90–95 per cent) are due to streptococci indistinguishable from those found in the normal mouth and upper respiratory tract Occasionally one is found which appears to have come from the intestine These streptococci are not hæmolytic, and have very little pathogenic activity for laboratory animals Further, they are not usually considered to be important agents in human pathology. although some workers dissent strongly from this view It is probable that they enter the blood stream from some focus in their natural habitat How often such invasion occurs without injury resulting is entirely unknown Experimentally, injections of such organisms may be made without ill-effects in many instances, but occasionally lesions of the valves develop What determines such a localisation is at present a mere matter of conjecture Clinically and experimentally it is known that previous injury of the valve predisposes to infection, and the same has been proved regarding congenital abnormalities How this is brought about and if abnormality of structure is a necessary pre-requisite are questions which remain to be determined It has been suggested that the localisation is due to an elective affinity which the organisms have for the valve tissues , that the tissues are specifically sensitised to the organisms by previous disease or invasion of the blood , that the effect of injury is purely mechanical None of these contentions can be regarded as adequately substantiated The precise relation of the disease to acute rheumatism can be settled only when the cause of the latter is definitely decided The is the case—perhaps more prominent in argument than in actual experience—where a woman is pregnant as the result of a criminal assault forcibly committed upon her against her will This case is clearly distinguishable from those where an unmarried woman is with child as the result of voluntary intercourse There is no legal authority for saying that it is lawful to terminate a pregnancy caused by criminal assault, but, if the practitioner is satisfied of the facts, he can operate with the certainty that juries will be slow to convict and judges slow to punish For the rest he must remember that the procuring of abortion upon insufficient medical grounds is as unlawful now as formerly, though religious inhibitions may seem weaker, and though the frankness of modern speech and thought may suggest a change in the national conscience The question for him in each case is the physical and mental safety of his patient The answer in each case rests, therefore, really with the medical, not with the legal, profession

SMALL-POX OUT OF CONTROL

The epidemic of small-pox in the North of England has now reached a stage at which the spread of the disease cannot be controlled The popular distaste for vaccination is reflected in the attitude of local authorities towards their duties, and in many areas it has become impossible even to ensure that contacts shall be vaccinated or segregated The result has been a long series of associated outbreaks which have proved expensive and inconvenient In one place the disease has been dealt with as though it were deadly; in another it has been disregarded because it is so trivial And at the end of several years it can still be claimed that either of these policies has been justified by events, for it has been shown that small-pox can only be controlled by concerted action, and it has sometimes proved to be hardly worth controlling If, indeed, we could be certain that the disease will remain mild in character, it would probably be wise to let it run its course unchecked, the public could take its choice between vaccination and a disease no worse than chicken-pox, and in either event would gain immunity But it is impossible to feel any such certainty Statements by the medical officer of health for Sheffield and others suggest that it is already becoming more virulent, and the whole policy of the Ministry of Health in demanding that the epidemic should be taken seriously is, of course, based on the possibility of such a change for the worse Dr C V Chapin,[1] having searched without avail for any record in the United States of the derivation of a severe from a mild outbreak, suggests that a sudden change or (speaking in biological terms) mutation of the small-pox germ, occurred in South Africa or Florida 30 years ago But, even so, who is to say that a mutation in the direction of mildness may not be followed sometime by a mutation in the direction of severity ? As Sir Humphry Rolleston recently pointed out at the Medical Society of London, outbreaks of mild small-pox in the past have been frequent, and this should warn us against believing that the virus has undergone a permanent change of heart Mild outbreaks have in the past been succeeded by widespread and virulent epidemics, and the same thing may happen again

Should such an epidemic occur in this country, as is quite likely, the situation would be serious Failure to control small-pox in the North of England has brought the policy of universal pseudo compulsory vaccination of infants into further disrepute, and has given another handle to those societies which make it their business to increase the distaste of the public for this measure. The tenets of these societies are largely academic They object to vaccination on the ground that it is illogical and unpleasant to inoculate the perfect human body with unclean disease It is very doubtful, however, whether this is the aspect of vaccination which deters the bulk of the population from having their children protected More probably it is the idea of possible danger and certain malaise which disturbs the public mind, for it is a mistake to suppose that all the opposition is due to lack of imagination or crankiness Vaccination at the age of six months inflicts an infectious disease on the child at a time when its digestive mechanism is being rapidly modified, and many reasonable people, although convinced that vaccination will prevent small-pox, think that the advantages of immunity do not outweigh the disadvantages of its production Such minor qualms would disappear in face of an epidemic, but there is enough sense in the opinion—when supplemented by the nonsense of the antivaccinists—to make universal and full vaccination of infants (as theoretically enforced by Parliament) impracticable in this country at the present time And there is no settled policy in its stead All that happens is that when an epidemic of small-pox breaks out the medical officer of health does his best to frighten the public into wholesale vaccination, his success depending partly on his personality and partly on whether the disease itself seems dangerous to the people of the district This is an unsatisfactory way of meeting small-pox in a civilised community, and it is time that the alternatives were fully discussed

The first alternative is to let small-pox take its course, offering vaccination to those who prefer it In view of the likelihood of a virulent epidemic sooner or later occurring, to carry out this proposal would hardly be fair to a semi-educated population The second alternative is to modify our methods of vaccinating infants, so that sensible people will have no reason to fear and dislike them This suggestion is discussed by Dr J Parlane Kinloch in his Report on the Health of Aberdeen for 1926 Although, he says, no evidence has been obtained that ordinary vaccination at six months is harmful to the child's future well-being, any immediate disturbance of health can be obviated if parents can be persuaded to adopt vaccination and re-vaccination, as follows[2] —

"In the first place, the child when a week old is vaccinated on the arm with the smallest single site insertion compatible with a successful take Vaccinia developing in this way is extremely mild and causes no discomfort whatsoever to the infant, and no scarring results from this procedure The immunity from small-pox thus secured is, however, of shorter duration than the immunity provided by the full vaccination procedure at the age of 6 months . . and while children thus mildly vaccinated in the first week of life are protected during the pre-school years, revaccination at the school age must be procured if the danger from small-pox is to be avoided This can be achieved by revaccinating with the smallest single site insertion compatible with a successful take, or if revaccination to the extent laid down in the Vaccination Order is now desired it is of no serious import to the healthy child aged 5 years"

Dr A Drury, however, who edits the Supplement in which this extract appears, takes exception to influence of neuroglandular dystonia in producing certain changes in the body temperature during the premenstrual period Having eliminated the possibility of a febrile condition imputable to some form of organic disease in the pelvis or elsewhere, and especially early or latent bacillosis, there remain to be considered other ætiological factors and precisely the secretory functionality of one or more endocrine glands and the disequilibrium between the two antagonistic systems of vegetative life This is, moreover, what has been done by other authors who, occupied with the same argument, and meeting with symptoms of hypersympathismus and manifestations, more or less clear, of increased endocrine functionality, especially thyroid, have described a sympathetic fever, or fever associated with hyperthyroidism The observations of A P Cawadias and Mme Hovelacque may be mentioned in this respect The charts of Dr Avezzu s two cases show a premenstrual rise of temperature of two kinds (1) the monothermic type, the daily oscillations never reaching 0 5 of a degree centigrade, and (2) inverted distribution—i e, the axillary temperature being higher than the oral The former is never met with in any of the great varieties of fevers due to the direct action of a definite microbe or of its pyretogenous toxins. The latter anomaly has been noted by Lucatello in a particular group of subjects with thyroid disturbance of the hypersecretory type, the external axillary figure being greater than the internal oral by two- or three-tenths of a degree centigrade In both the cases described, Marañon's sign—friction of the prethyroid region causing erythema—Bram's test, tolerance to quinine, Goetsch s test, injection of adrenalin causing lowering of the diastolic with increase of the systolic blood pressure, and Porak's test, bradycardia, and glycosuria after injection of pituitrin all these were reacted to in a strongly positive manner To explain the pathogenesis of the increased premenstrual temperature, attention must be drawn to the functionality of the sanguineous glands during the cycle of maturation of the ovary—i e, that there is a displacement of glandular equilibrium such as to cause in every premenstruum physiological phenomena of hyperluteinism and of hyperthyroidism which are substituted for diametrically opposite conditions during the menstrual phase and the first few following days Most physiologists admit that the Graafian follicle ruptures about 12 days after menstruation, and the corpus luteum reaches complete secretory functionality on the seventeenth day, but continuing to increase up to one or two days from the sanguineous flow, at which period its involution begins which is completed eight days after the menstrual period In the case of pregnancy the corpus luteum remains active for a long time and its secretory activity fades only about the third month The hyperthermia therefore, whether premenstrual or gravid, follows on parallel lines the evolution of the corpus luteum and seems to be closely connected with it

THE DIETARY VALUE OF THE SOY BEAN

FOR the last 2000 years the soy bean has been used in North China for making bean curd, a thick nutritious jelly eaten daily by all classes of the people A vegetable oil is also expressed from it and is widely employed, the refuse serving for cattle-food and manure for sugar plantations About 100 years ago the bean was introduced into England, but no attempt was made to cultivate it and it is only during the present century that its remarkable merits have aroused interest English firms have taken a large part in its export from Manchuria and as long ago as 1911 the amount exported rose to about half a million tons annually In 1910 experiments were begun which demonstrated that the soy bean could be grown throughout South Africa and its cultivation there was strongly advocated [1] It was shown that besides being useful for animals, it could form the basis of substitutes for flour meat, chocolate, macaroni, cheese, and coffee, and a few years later much interest was aroused in this country by an attempt to exploit a soy bean product as "synthetic milk"[2] That from the standpoint of nutrition this attempt was not unjustified is evident from the descriptions and analyses of the bean which we have from time to time published, but it has been found difficult to popularise its use owing to the disagreeable digestive disturbance to which it may give rise Even under the stress of the late war its general adoption was found impossible in Germany In an article which we publish on page 267 Prof T. R. Parsons shows that a new phase has been entered upon, owing to the discovery by Dr Berczeller in Vienna that the obnoxious constituents of soy bean can be removed by special milling and fractional distillation without interfering with the high nutritional value of the resulting meal Prof Parsons bases on these facts a well-considered appeal for an investigation on a large scale, hazarding the opinion that Haberlandt's prescience may yet be realised and the soy bean come to be extensively utilised in the diet of the masses to supply the proteins and fats needed in supplement of the abundant carbohydrate which they obtain from the potato His facts and figures should certainly receive the attention of all who are interested in the feeding of men or animals

MOVING RADIOGRAMS.

APART from its use for purposes of demonstration, it has long been evident that the cinematograph might be of much value for research if continuous pictures illustrating the passage of opaque meals could be obtained Many technical difficulties have stood in the way, direct pictures could not be taken, as the size of the ordinary X ray shadow would necessitate the use of enormous films; the employment of an indirect method, in which ordinary photographs are taken of the image seen on a fluorescent screen presents other difficulties, such as protection of the patient and camera and the securing of a sufficiently bright image For nearly six years Dr Russell J Reynolds has been grappling with these and a score of equally awkward technical difficulties, which he described in full in a communication to the Rontgen Society on Jan 11th We are glad to note that he is now able to secure satisfactory moving pictures of the bony parts, although his apparatus is not yet sufficiently perfected to enable him, we gather, to get serial views of the viscera in action When we consider the advance that has followed the study of the kinetics of the heart as revealed, however imperfectly, by the electrocardiogram, and the change in thought that has occurred since recognition of the fact that the dissecting-room gave an illusory picture of the anatomy of the alimentary canal, it seems clear that if, as the result of Dr Reynolds's researches, we become able to get clear moving pictures of these viscera, great advances in medical physiology and clinical medicine may result Phenomena such as the mass peristalsis of the colon, or the mechanics of the duodenal cap call for considerable elucidation Applied pharmacology may reveal the secrets hidden to-day under the names of vagotonia and sympatheticotonia Experiments have already been made to study the intimate movements of the heart by means of the slow-motion cinematograph, but these and other inquiries are held up by the relatively immense costs We say relatively immense, for it is true that such sums are trivial in comparison with those expended by modern "photo play" producers when seeking some realistic reconstruction of the Tower of Babel or the Burning of Moscow It seems reasonable to hope that in the near future some hero or heroine of the "movies" may divert a portion further interesting feature of the subacute form is the long-continued septicæmia This has been regarded as due to a failure of the patient's eliminating mechanism. So far as can be judged this view is not correct, for the majority of patients have a markedly increased amount of antibodies, and their blood is quite unsuitable for the growth of the organism Others believe that the organisms develop enhanced resistance to the destructive agencies at the patient's command Others again have sought the explanation in the anatomical peculiarities of the lesion which prevent the access of cells to the organisms These then multiply in the vegetation and escape mechanically into the blood, remaining there, without multiplication, until they are removed and destroyed It is well-known that though infarction and embolism are common, suppuration is very rare There is no evidence that treatment on specific lines has any effect on the condition The same may be said of all other methods

[2] THE LANCET, 1912, ii, 1095

Infective endocarditis is merely a special case of the localisation of infecting agents A full understanding of it involves consideration of certain problems peculiar to its anatomical situation, thrombosis and vascular injury, and of others of a more general interest, the nature of bacteriæmia, the mechanism of defence against the streptococci, the classification of the streptococci The therapeutic problem is that of an inoperable focus of chronic infection rather than that of a pure bacteriæmia Solution of the problems of infective endocarditis would be a large contribution to pathology, and for its solution search may have to be made in fields far removed from human cardiology, not least perhaps in the realm of comparative pathology The Secretary of the Research Fund is Dr P SEYMOUR PRICE, of 41, Sloane-gardens, London, S W 1, to whom information should be sent Scientific workers and clinicians are invited to communicate with him as to lines of research which they think likely to prove helpful

◆

THE DANGERS OF GASEOUS ANÆSTHETICS

THE increasing use of chemically active gases as anæsthetic agents should bring home to the administrator the great need of care to avoid the risk of ignition or explosion Nitrogen is such an inert gas that the impression has got abroad that nitrous oxide is also inert, the practitioner having forgotten his early days in the chemical laboratory when a glowing splinter thrust into a cylinder of this gas broke into flame, much as it would have done in oxygen For nitrous oxide contains nearly twice the proportion of oxygen in the atmosphere At the request of the Joint Anæsthetics Committee of the Medical Research Council and the Royal Society of Medicine Prof H B Dixon, F R S, has been conducting a series of researches on the burning of gases in nitrous oxide full details of which have been published in the Proceedings of the Manchester Philosophical and Literary Society (vol lxxi, Dec 10th, 1926), and we are happy to print on another page a short account by the author of his results From this it appears that nitrous oxide is even more active than oxygen itself in supporting the ignition and explosion of such anæsthetic agents as ethylene and propylene The Committee thinks it advisable to warn anæsthetists and the medical profession generally of this fact, ignorance of which might lead to a serious or even fatal explosion

VOL II, 1926

THE Index and Title-page to Vol II., 1926, which was completed with the issue of Dec 25th, is now ready A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

Annotations.

"Ne quid nimis"

PSYCHOLOGICAL EXPERIMENT BY WIRELESS

AN initial difficulty in the collection of data for psychological study is that of obtaining a random and sufficiently large sample of human material An investigator may have access to groups of people in schools, colleges, factories or offices, but a large sample of the public selected without reference to age, sex, social position, education, or occupation, can rarely be made the subject of the simplest investigation Prof T. H Pear has, therefore, been favoured with an almost unique opportunity in the experiment just conducted by him with the aid of the British Broadcasting Corporation, for the only factors involved in the selection of his material were the opportunity to listen and the will and ability to write a short report He arranged that nine speakers should in turn read the same passage—a fragment from "Pickwick Papers" was chosen—and the public were invited to listen to the voices thus broadcast and answer a set of questions about the sex, age, birthplace, profession, and accent of each speaker, and to express a judgment as to whether he or she was likely to be capable of leading others The primary aim was to ascertain whether there is any general accuracy in such conclusions when they are based solely upon the voice, but from the psychological department of Manchester University we may confidently expect other interesting results from the thousands of replies that Prof Pear has certainly received Each reporter is asked to state his name, address, and occupation, and on this basis the replies may give information of philological interest, for the detection of the locality indicated by an accent would, we may expect, vary with the locality of the listeners To some Londoners, as a negative example, the accent imparted to the words of Sam Weller suggested that one speaker was a stranger to the dialect of London, and the positive diagnosis of a specific accent might come with especial frequency from the district where it prevails Besides the direct aim of estimating the validity of judgments based upon the qualities of a voice, we may expect other results to emerge from the statistical examinations of the sex, address, and occupation of the reporters What people show interest in this experiment? Is occupation or station in life correlated with accuracy of judgment? Do men or women make the wildest shots? Perhaps these questions may not be answered, but if the statistical machinery of Manchester University is capable of dealing effectively with the material obtained, we hope to see other interesting results from a mass experiment that would have been impossible before the general use of wireless

THE MENSTRUAL TEMPERATURE CYCLE

VARIATIONS in body temperature dependent on critical periods in females, and especially on menstruation, associated with organic disease and particularly with tuberculosis have been dealt with by various observers In more recent years changes in the endocrine glands have been shown as possible sources of disturbance of thermogenesis, and menstruation, or as it is better called, the ovular cycle, has begun to be considered, independently of any other pathological condition, as the determining cause of excessive thermic variations Excluding all those cases in which hyperthermia could be referred to pathological conditions in some organ or system, the number of clinical observations on subjects showing, during the premenstruum, a temperature above normal have been very limited Dr G Avezzu, of the University of Padua, has published[1] two interesting cases which bear on the subject of the than a mere collection of useful pieces of knowledge, it should rank as an educational influence and become an integral part of a man's life Only when hygiene and ethics go hand in hand can success be achieved; the hardening of the body and its exercise require fortitude and self control, abstinence from alcohol, tobacco, and similar amenities imply a strong sense of responsibility. Dr Vogel makes interesting suggestions as to the part that the clergy should play in the inculcation of hygiene, he considers the close connexion between health and morality to be adequate reason for demanding their intervention in such important problems as the diminution of the birth-rate, abortion, and in the struggle against infectious and venereal disease and alcoholism Anyone who sets out to teach must set a good example, the fact that 10 per cent of the Evangelical clergy are organised abstainers is, in his view, more valuable to the cause of abstinence than many of the lectures delivered on the subject Dr Vogel deals with hygienic teaching in schools and holds that the syllabus of the teacher should include anatomy and physiology as well as hygiene stress being laid on knowledge of function rather than structure

---

[1] Il Policlinico, Medical Section, Dec 1st, 1926

"Parents' days" (Elternabende) give the school doctor and teacher an opportunity of instructing the parents in the care of their children Adult instruction in health matters is dealt with even more fully The lecturer should arrange for the audience to be composed of people with common interests, in the same rank of life, with the same standard of education and intelligence Dogmatism is not essential, no harm comes from confessing the limitations of our knowledge so long as the lecturer himself is quite clear as to what is established and what speculative. The lecture should be a compact whole, not a collection of unrelated fact; it should be personal and concrete; to avoid superficiality the scope of the lecture should not be extensive Pictures are helpful but should be carefully chosen and easily followed Dr Vogel warns lecturers against showing too many slides at a lecture; 40–50 are enough for any audience, 12–20 suffice for children Only a few slides difficult to understand, such as statistical slides, should be included He does not approve of a prepared lecture being read out to explain the slides, the explanation of the slides themselves should constitute the lecture, although care should be taken to introduce personal touches; the Dresden Hygiene Museum has prepared discourses on these lines to accompany the sets of slides He has not much use for hygiene films, the dramatic representation often takes place in other spheres of life to that in which the audience lives He instances films on mothercraft which show nurses in well-equipped institutions using a water spray to rinse out feeding bottles, the mother thinking of her humble appliances at home at once decides that proper rinsing of feeding bottles is beyond her capacity Moreover, the scenes pass so quickly that only persons of sharp intelligence can grasp the lesson it is intended to convey A form of propaganda referred to is the Health Calendar, not, so far as we know, used in this country. Social hygiene must be explained by examples taken from life, or by preparations, drawings, or models At the beginning of this century very little suitable material was available in Germany, but the Dresden Hygiene Museum has done much to fill the gap By imparting life and plasticity to anatomical and pathological presentations it has taken away their frightfulness, by emphasising the important, it has done away with the dangers of schematization, by care in fixing the size of the pictures, choosing carefully colours and backgrounds and the character and arrangement of type, placards have been made attractive as well as arresting Lingner, the founder of the Museum paid especial attention to the representation of statistical facts in graphic form, here representations of human figures and articles of different sizes can be made to play a useful part Dr. Vogel notes with pain that the usefulness of museums and exhibitions is limited by the difficulty of getting enough people to visit them A separate division of propaganda must thus be set up for their advertisement

Dr Vogel thus gives a good outline of the progress of health teaching in Germany, including many hints which will be useful to those in other lands The problems of all modern civilised States are much alike, and we may note in passing the inter-urban rivalries An excellent bibliography of the whole of the subject is given by Dr. Vogel; its comprehensiveness emphasises the omission of all reference to the Volkshygienisches Museum at Cologne and its Director Dr Czaplewski

ACUTE THYROIDITIS

Dr H M Clute and Dr L W Smith[1], of the Lahey Clinic and Pathological Department of the Harvard Medical School, give the following statistics to illustrate the extraordinary rarity of acute thyroiditis as compared with acute suppurative inflammatory processes of other glands Hagenbach found only 43 cases among 45,953 medical and surgical admissions to the Basle Clinic during a period of ten years In a recent series of nearly 1200 cases of thyroid disease in the Lahey Clinic there was only one case of frank suppurative pyogenic thyroiditis, one of tuberculous thyroiditis, and five of chronic inflammatory strumitis of the Riedel type In no case seen during 1925 was a clinical diagnosis of acute thyroiditis made. and before that date the writers had seen only four patients in whom this diagnosis was established Only three out of over 3000 thyroid operations in the Lahey Clinic had been done for thyroiditis with abscess formation The rarity of the condition is explained, first, by the thyroid being well encapsulated and not communicating with the pharynx, except when the thyroglossal duct persists, secondly, by its unusually rich lymphatic system, which facilitates free drainage of the gland; and thirdly, by the bactericidal action of the thyroid secretion Although acute thyroiditis may occur in children secondary to various acute infections, it is most frequent in young adults. probably owing to the changes in the physiology of the thyroid gland which accompany active sexual life Infection in the upper or lower respiratory tract such as Vincent's angina, influenza, or pleurisy frequently precedes the onset of acute thyroiditis Cases have been reported as developing during typhoid or paratyphoid infections, but such an occurrence is very uncommon The onset is usually acute and marked by fever, chills, and pain in the throat and neck Difficulty in breathing occurs early and increases rapidly if an abscess forms A hacking cough and a sense of fullness in the neck is present The voice may be hoarse, but complete aphonia is unusual. Dysphagia is frequently present, especially in association with suppuration Symptoms of hyperthyroidism may develop The physical signs are characteristic. Though swelling is not prominent, unilateral or diffuse enlargement of the thyroid can often be detected. The disease runs a benign course, usually lasting six to ten days Abscess formation is very rare in simple thyroiditis, but may occur in from 60 to 70 per cent of goitrous cases Other complications are œdema of the larynx, broncho-pneumonia, and chondritis and perichondritis of the larynx Exophthalmic goitre may develop and subside with the thyroiditis or persist after the acute symptoms have disappeared. Acute thyroiditis must be distinguished from hæmorrhage into a thyroid adenoma, which follows exertion cellulitis of the neck, or isolated perichondritis of the trachea or thyroid cartilages In the absence of abscess formation the prognosis of acute thyroiditis is excellent Healing occurs rapidly and completely and recurrences are rare The treatment is symptomatic On the occurrence of suppuration early incision and drainage under gas-oxygen anæsthesia are indicated.

of his or her colossal earnings from entertainment to inquiry—may we say, from therapeutics to research.

A CASE OF RAT-BITE FEVER

Miss G M Herzfeld and Dr T J Mackie[1] have recently described a case of rat-bite fever in a child, 5 years old, who had been bitten on the forehead by a rat a month before admission to hospital Fourteen days after the bite was inflicted the healed wound became inflamed and the cervical glands swollen, but the symptoms subsided under treatment, and the child seemed well until two days before admission, when the forehead became swollen again and the temperature rose to 102° F Four relapses occurred in hospital. Finally, the gradually enlarging cervical glands were excised, and the child was treated with salvarsan and recovered rapidly The interest of the case—apart from the rarity of the disease in this country—lies in the difficulty which was experienced in demonstrating the presence of the causal organism of rat-bite fever, *Spirochæta morsus muris* or (as has been suggested) *Spirillum minus*. The blood during a febrile attack, fluid from the inflamed area around the bite, and the urine were all examined directly by culture and by animal inoculation, without showing the presence of the spirillum It was not until the excised glands were searched that the spiral organisms were found, both in direct films from the glands, stained by Leishman's method, and in the blood of guinea-pigs inoculated with the substance of the gland From the blood cultures made during fever a motile bacillus was isolated, growing abundantly on ordinary media under aerobic conditions and corresponding to *Bacillus fæcalis alkaligenes* This organism, when tested against the patient's serum, was agglutinated in a serum dilution of 1 in 320 ; five days later the titre had risen to 1 in 1280, which indicates that the bacillus was responsible for a definite hæmic infection. This organism was a secondary invader, but owing to the difficulty of demonstrating the spirillum, the true extent of the disease might easily have been overlooked, in which case the bacillus might have been regarded as the causal organism

PERFUMES AND SCENTS

Smell, being one of the earliest evolved of our senses, is connected with some of the deepest of human instincts, and perfumery is one of the most ancient of arts It probably had its origin in the discovery by primitive man that the twigs of certain shrubs or trees imparted an agreeable smell to the smoke of the cave fire, and scents are associated with every religious system of which we have any knowledge To make a present of perfumes was among Eastern people an expression of profound respect The Magi presented the Holy Child with frankincense and myrrh , incense burns in the temples of every faith, and kings are anointed with fragrant oil. Anyone who takes an interest in the subject will find a valuable guide in "Fragrant Flowers,"[2] recently published by an authority on herbs This study is chiefly concerned with the plants and processes used in the present-day manufacture of perfumes, but incidentally it contains some data about the use of perfumery in medicine The antiseptic value of essential oils has been determined in the laboratory by exact experiment, but long before this was done physicians had a profound faith in the medicinal value of strong scents The priests of ancient Greece chewed bay leaves to induce prophecy, and recommended their use in pillows as a hypnotic measure. The strong odour of these leaves was also supposed to protect against infection, and in times of plague the refugees from the country round Rome would congregate in Laurentium, named for its abundance of laurel bushes The action of sunshine on cherry, laurel, clove, fennel, and other aromatic plants is now known to release ozone, and thus an early superstition, like so many others, has the support of recent exact knowledge John Evelyn put forward a scheme which entitles him to rank as a pioneer of the garden city movement He suggested that all low ground near London should be planted out with pinks, lilies, thyme, and other scented plants, intersected by hedges of sweet briar, rosemary, and the like He was a believer in the purifying power of plant odours, and knew nothing about carbon dioxide or ozone, but all authorities on public health to-day agree that parks and gardens are vitally important to the welfare of large towns Mrs Grieve quotes the statement of Ungerer, a leading perfume manufacturer of the last century, that tuberculosis was rare in the flower-growing districts of Southern France, and that workers in perfume laboratories were singularly free from respiratory infections She claims the greatest antiseptic power for thyme and origanum, followed by verbena, cassia, and cinnamon Everyone who has visited the Wellcome Historical Medical Museum knows the pomander-sticks carried by physicians of olden times to protect them from infection The pomander of Tudor times was a little ball of perfumed paste, made with aromatic gums pounded with rose water and blended with wax or apple pulp (whence the name) It was originally carried as a prophylactic against infectious disease, but later became a luxury and gave the jewellers of the period a medium on which to exercise their ingenuity and skill in the construction of pomander boxes Vinaigrettes, a similar invention, gave more wholesome scents than the sachets of synthetic perfume that have superseded them Apart from their antiseptic qualities scents have well-defined effects on the nervous system, as everyone realises who carries the right flowers to a sick-bed or sprays eau-de-cologne on the pillow of an invalid, and there may be room for useful research on these lines

THE TREND OF HEALTH EDUCATION IN GERMANY.

In ancient times the practice of hygiene was inculcated by its propaganda in the form of religious commands, it was part of the life of the people, at the present day, in spite of our greater knowledge, hygiene is not a living educational force among the masses of the people For this probably the sanitarians of last century were responsible, hygienic problems were looked at too much from the physico-chemical standpoint, and sufficient attention was not paid to the fact that man is a living organism No hygienist 20 years ago would have anticipated the scientific interest taken to-day in physical exercise and in bathing in light, air, and water The contrast between the importance attached to various health measures in 30 years is well brought out in the historical introduction to an article contributed by Dr Martin Vogel, the Scientific Director of the Dresden Hygiene Museum to a manual of social hygiene[1] recently published in Germany He compares the first German Hygiene Exhibition held in Berlin in 1882–83 with the 1911 International Hygiene Exhibition at Dresden At Berlin defence against disease was considered entirely from the point of view of disinfection, school hygiene was chiefly concerned with the form of the school desk, there was no material for the instruction of the public in health Thirty years later in Dresden the exhibition was centred round the building dealing with "der Mensch"; new ways especially thought out for the purpose were used to try to bring home to the man in the street the wonders of the human body and to place before him the discoveries of scientific hygiene Dr Vogel holds out that it is not enough to merely give people health rules, for instance, how they should cough; hygiene should be more facture a serum in Europe from the poison of African vipers, which are probably easier to obtain in large quantities than the European reptile

STRANGEWAYS MEMORIAL

A meeting will be held at the Royal Society of Medicine on Wednesday, Feb 2nd, at 5 P M, in support of an appeal arising out of the premature death of Dr T S P Strangeways, which was recently recorded in The Lancet Dr Strangeways left a widow and seven children, the five youngest of whom are still being educated, and all the circumstances will elicit the deep sympathy not only of his colleagues and workers along his special lines, but through the whole medical profession It is known to many that any part of his income which was not required for household expenses was habitually used by him to assist the Research Hospital at Cambridge, he could never divorce personal needs from those of the work he was passionately engaged upon The immediate position of the family has been met by subscriptions from friends in Cambridge, but a large sum will be required to complete the education of his sons, the eldest of whom is in his second year at Trinity Hall. During the last 30 years a very large number of medical men graduating at Cambridge have been taught by Strangeways the essentials of pathology, and these men in particular may feel that this is an opportunity of expressing their appreciation of his work, but the additions to medical knowledge made by him, as well as his self-effacing enthusiasm, give the family a claim upon all medical men The appeal is now open and cheques should be drawn to Lloyd's Bank, Cambridge, and crossed "c/a Strangeways Memorial Fund" They may be sent to Mr G F C Gill, manager of the bank, who has kindly consented to take charge of the account, or to Sir Humphry Rolleston, Southfield, Cambridge, to Prof H R Dean, Dr M Donaldson, Dr G P Bidder, Dr L E Shore, or Dr Cobbett We hope that the meeting at the Royal Society of Medicine on Wednesday next will be fully attended by those who sympathise with an appeal that is alike urgent and well justified

---

Sir Ernest Hodder-Williams's condition indicates that during the past week he has made satisfactory progress

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Comdrs J C Bringan and G B Scott are placed on the Retd List with the rank of Surg Capt

Surg Lt.-Comdr H C A Tandy-Cannon is placed on the Emergency List

Surg Lt (D) E G Adams to be Surg Lt -Comdr (D)

T Prentice, P H Deeny, C R Boland, and G Rorison to be Surg Lts

ROYAL ARMY MEDICAL CORPS

Capts W C Hartgill, J H Baird (Prov), and F Harris (Prov) to be Majs

ARMY DENTAL CORPS

Maj J G Worsley (Temp Sqdn Leader, R A.F) retires

Temp Capt W A Cowden, Dental Surg , Gen List, to be Capt

TERRITORIAL ARMY

Lt -Col J W Kemp to be Bt Col

2nd Lt. W L Kinnear, late 4th/5th Bn Black Watch, to be Lt

Lt J F Fraser, from the Gen List, T A., to be Lt with precedence and to be supern. for serv with the Med Unit, Aberdeen Univ Contgt Sen Div , O T C

R A M Scott to be Lt

ROYAL AIR FORCE

The undermentioned are granted short service commissions as Flying Officers, for three years on the active list J E Foran and M O'Regan

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCVIII —TREATMENT OF UNUNITED FRACTURES

I General Principles *

In recent years much light has been thrown on the processes of bone repair both by animal experiment and also by practical experience with the mass of bone injuries and ununited fractures left in the wake of the Great War Now, too, the increasing frequency of street accidents makes the subject of the treatment of ununited fractures one of growing importance

As in many other branches of surgery, the most effective and desirable form of treatment is preventive Moreover, the treatment of each individual case is so much guided by the factors causing the non-union that it is necessary to survey briefly the common causes of the condition before discussing the relative values of different methods of treatment

Before proceeding to the operative treatment of a case of ununited fracture, it is important to diagnose the cause of the non-union, since if this is not merely a mechanical one which can be eliminated at the operation the same factors will continue to act and will almost certainly mar the final result

Causes of Failure to Unite

General causes of non-union include conditions which lower the bodily vitality in any way—e g , acute illness , chronic diseases like nephritis and tabes , other conditions which directly upset the calcium metabolism of the body, such as the various types of fragilitas ossium, scurvy, and rickets , various obscure diseases of the ductless glands , and old age in which the processes of decalcification normally outrun those of ossification

Local abnormalities of the bone such as the presence of a tumour or a cyst, which may itself have been the original cause of the fracture, can usually be diagnosed by X rays, and should always be suspected when a fracture occurs after very slight violence

Other local causes are usually *mechanical*, such as the interposition of muscle or periosteum between the bone-ends, and if such are known to exist, or are strongly suggested by the X rays, operation should not be delayed Another local complication is *injury to the nutrient artery*, and recent experiments on animals suggest that this plays an important part in the production of the non-union

In the treatment of fractures it must always be remembered that bone is a living, varying structure, not constant in shape and density like the leg of a table Every bone in the body is the constant subject of a double process—i e , simultaneous destruction and reconstruction The balance of these two processes is influenced by age, disease, and accident In children the constructive process predominates, giving increase in length, width, and density to the bones In old age the destructive phase is the prominent one, so that the bones become more porous and brittle It is evident, therefore, that fractures in children are likely to be followed by rapid union, but there is a danger of excessive callus formation, which may interfere mechanically with neighbouring joints in the fractures of old age, on the contrary, union is likely to be delayed, but the vigorous manipulations that stimulate it can be resorted to without fear of inducing excess of callus

With regard to the function of the periosteum, it seems to be generally agreed now, after much swinging of the pendulum, that the fibrous layer acts as a limiting membrane, to keep the bone-forming elements within due limits , while on the other hand, some of the most active of these cells are to be found just under the membrane, on the surface of the bone Accordingly, when the periosteum is torn there is a risk of the formation of exuberant spurs of bone , but if it gets between the bone-ends at seat of fracture it may so check new-bone formation as to cause non-union This is a very frequent finding with transverse fracture of the patella

---

* The Treatment of Ununited Fractures—II Special Fractures —by Miss Forrester Brown, will appear next week

TROPICAL MEDICINE IN THE FAR EAST.

If a bulky volume be any index of a successful meeting, then the Sixth Congress of the Far Eastern Association of Tropical Medicine must have transcended all its predecessors In the 1197 pages of its transactions[1] is contained a variety of pabulum to suit the most catholic of tastes There are no less than 149 original contributions, and the subjects range from tatooing and dentistry to elaborate biochemical and metabolic studies The Congress was inaugurated with an eloquent address by the Prime Minister of Japan, Viscount Takaaki Kato, followed by Prof Shibasaburo Kitasato, whose name is familiar throughout the medical world Appropriately enough, the subject of beriberi and nutritional diseases occupy quite one quarter of the volume, and it is a matter of very considerable ecological interest that undoubted pellagra has been recorded in Japan by Dr Minoru Itoh There are many papers of helminthological interest, such as studies on clonorchis infection, on the lung-fluke (paragonimus), by H Kobayashi, hookworm infestation among Japanese immigrants and residents, the pathology of *Schistosomum spindale* by Dr N H Fairley and Lieut-Col F P Mackie, and a differential table of 17 species of schistosomes, by B Tanabe, which affords, for the first time, an accurate synopsis of the subject Anthropology has not been neglected, for there are studies of the racial indices and characteristics of the aboriginal Ainu and other folk from Saghalien and China The great majority of the contributions are written in English or German languages, though there are a few from Indochina in French The secretaries of this meeting, Dr S Hata and Dr Y Miyagawa, are to be congratulated on the efficient manner in which they have completed their unenviable task in collecting this heterogeneous matter into one volume, the printing and binding of which leave nothing to be desired

THE GENESIS OF GASTRIC PAIN

The common association between gastric and duodenal ulcer and high concentrations of hydrochloric acid in the stomach is too well-known to require comment, but the actual part played by the acid in the genesis of gastric pain is not yet fully understood On the one hand, the word hyperchlorhydria reminds us that to a great many physicians some excess of acid in the stomach may by itself be the explanation of unusual symptoms, on the other hand, the work of A F Hurst and others, and of Izod Bennett and others, teaches us that not only does the introduction of strong acid into the normal stomach not induce pain, but that when a large number of normal stomachs are examined cases are not infrequently encountered in which the normal acidity is fully as high as that met with in disease The subject of the mechanism of pain in gastric and in duodenal ulcer has recently been further investigated by Dr W L Palmer,[2] who has introduced acids and other chemical irritants into the stomachs of patients suffering from peptic ulceration With normal men he found that the introduction of 0 5 per cent hydrochloric acid solution caused either no sensation at all, or at most one of slight epigastric burning In patients suffering from gastric or duodenal ulcer, on the other hand, such injections led to the immediate occurrence of pain which the subjects described as indistinguishable from their normal pains The fluids used for such injections were of interesting variety Sometimes the patient's own acid stomach contents were removed, their reinjection subsequently producing typical pain, in other cases solutions of hydrochloric or sulphuric acid were employed with similar effects Sodium hydroxide in tenth-normal solution produced similar pain, the symptoms in both acid and alkali experiments disappearing when the stomach had by secretion or regurgitation reduced the strength of the exciting chemical to something approaching normality Some of the patients were seen at periods when they were without symptoms, and it was found that in these circumstances the introduction of acid provided no sensory response In general, Dr Palmer concludes that the gastric acid acts as a true chemical irritant to the pain-producing mechanism, the variable factors on which the production of pain depends being (1) the sensitiveness of the pain-producing mechanism, (2) the concentration of the acid, (3) the amount of acid used (4) time (5) the rate of emptying of the stomach, and (6) the rate and amount of duodenal regurgitation These experiments seem to produce confirmatory evidence in favour of the view that, whilst the gastric hydrochloric acid is normally responsible for the excitation of pain in gastric ulcer, it is necessary for an ulcer or other pain-producing factor to be present before this symptom can be aroused The term hyperchlorhydria is, in short, misleading, and should disappear from diagnostic nomenclature In this connexion it is interesting to note Prof M T Finney's statement in the discussion reported on page 228 that the action of gastric juice does not prevent the rapid healing of artificially produced defects so long as there is no interference with the blood-supply

ANTI-VIPER SERUM

The serum treatment of snakebite is now well established in India, South America, and other countries where deadly snakes are common, but although there are a fair number of casualties every year from the bites of vipers in Europe, little has been done to provide an efficient seral antidote The demand for it may be small, inasmuch as only a small proportion of viper bites are fatal, but the great hindrance to its production lies in the fact that, vipers being much smaller than cobras and rattlesnakes it is difficult to obtain sufficient venom for practical purposes Colonel M L Crimmins[1] states that it takes as many as 200 rattlers to give 60 c cm of venom The only European source of anti-viper serum at present is Prof Calmette's laboratory at the Pasteur Institute, where the poison used is that of *Vipera aspis*, but Prof R Kraus, of Vienna, has recently demonstrated that the antidote need not be rigidly specific[2] He has experimented with two other sera besides that of Calmette, one prepared from the blood of animals inoculated with the poison of *Lachesis jararaca*, and another taken from blood rendered immune to the mixed poison of several South American vipers He found that the first of these would not only neutralise the poison of *Vipera aspis* when mixed with it but was as effective as Calmette's serum when injected separately into an inoculated animal He points out, however, that this serum contains two separate antitoxins, which have similar properties in vitro but not in vivo—a discrepancy which has been already remarked on by workers on antidiphtheric and antidysenteric sera The antilachesis preparation would neutralise a dose (0 03 mg) of aspis poison sufficient to kill a normal guinea-pig in 1–3 hours, and should therefore, Prof Kraus considers, be effective on human subjects suffering from the bites of European vipers The second preparation, which has the formidable name of "Vital Brazil polyvalent anti-Bothrops," proved as efficient as Calmette's serum, 1 c cm saving guinea-pigs after a dose of 0 025 mg of aspis poison, and 3 c cm after a dose of 0 05 mg—a control animal dying in one hour from the effects of 0 025 mg While Prof Kraus's experiments thus indicate a second existing source of efficient anti-viper serum, it would be inconvenient for clinicians to rely on a South American remedy, and it is to be hoped that further experiments will be made nearer home It might, for instance, be possible to manu-

Special Articles.

ON THE IGNITION-POINTS OF GASES IN NITROUS OXIDE

By H B Dixon, C B E, D Sc F R S,
Hon Professor of Chemistry in the University of Manchester

At the request of the Anæsthetics Committee of the Medical Research Council and the Royal Society of Medicine, I have made experiments on the ignition-points of certain gases when introduced into an atmosphere of nitrous oxide, and have compared such ignitions with those of the same gases in air and in oxygen The two gases, ethylene and propylene are of special interest medically on account of their proposed use in producing anæsthesia, and of the great violence with which these gases may explode when mixed with oxygen or air, or with other supporters of combustion such as nitrous oxide

On consulting the literature of the subject it was surprising to find how little the flames of gases in nitrous oxide had been studied Joseph Priestley, when he discovered the gas in 1776—calling it 'Dephlogisticated Nitrous Air"—describes a candle as burning in the gas with a much enlarged flame, sometimes twice as large as it is naturally, and sometimes not less than five or six times larger" Humphry Davy also observed the increase in size of the candle-flame when plunged into the gas He seems to have formed the opinion that the heat of the burning body first decomposed the nitrous oxide, and that the combustion was the result of a direct union with the liberated oxygen "Inflammable bodies in general," he writes, "require for their combustion in nitrous oxide much higher temperatures than those at which they burn in air or in oxygen" Most modern writers appear to have followed Davy's opinion, but our experiments are not in accord with this view All the gases tested in our apparatus have *lower* ignition-points in nitrous oxide than in oxygen, and these ignition-points are found at temperatures below that at which the thermal decomposition of nitrous oxide is appreciable

Hydrogen

As the burning of hydrogen in oxygen is probably one of the simplest of the "flame" reactions initiated at a definite temperature, it was natural to start the investigation of flames in nitrous oxide with that of hydrogen

On bringing an atmosphere of nitrous oxide round a small jet of hydrogen which is burning in air with a non-luminous flame, the change observed in the character of the flame is most remarkable · the diameter of the flame is doubled, while its height is multiplied by five The central core (of a pale apricot colour) becomes luminous, and the spectrum given by it appears to be continuous from red to violet

In the following determinations a steady flow of nitrous oxide was passed upwards through a large cylinder, while a jet of hydrogen was introduced from time to time from a narrow central tube opening in the middle of the cylinder The lags between the moment of contact of the two gases and the appearance of the flame were noted, as the temperature of the furnace rises the interval ("lag") between the issue of the gas and its ignition gradually decreases until this becomes half a second, the current is then reduced and the temperature allowed to fall slowly A second series of observations are then made while the "lag" gradually increases The mean of the ascending and descending readings for each lag is taken as the ignition-point for that lag The two series of readings (with rising and falling temperatures) were usually repeated five or six times and the average of all the readings taken

Experiments were made at pressures varying from 1000 mm pressure down to 150 mm , the *averages* of the readings are given in Table I and (for comparison) the averages found for the ignition-points of hydrogen in oxygen taken from the curves at the corresponding pressures

Table I —*Ignition-points of Hydrogen in Nitrous Oxide and in Oxygen at Different Pressures*

Pressure	1000 mm		760 mm		550 mm		400 mm		250 mm		150 mm	
Atmosphere	N_2O	O_2	N_2O	O_2	N_2O	O_2	N_2O	O_2	N_2O	O_2	N_2O	O_2
Lag—												
½ in	594°	627°	597°	625°	572°	611°	549°	591°	524°	563°	504°	533°
1 in	587	620	588	618	562	604	540	585	518	55[illegible]	497	531
2 in			577	606	554	598	534	575	513	552	491	528
3 in			571	596	548	587	530	569	509	550	487	526
5 in			562	588	543	578	526	566	505	548	484	—

It is evident from these figures that the ignition of hydrogen in nitrous oxide at different pressures follows the same general rule that governs the ignition of hydrogen and other gases in oxygen and in air There is a crucial pressure—about that of the atmosphere—above and below which the ignition-point falls In every case the ignition-point of hydrogen in nitrous oxide is *lower* than in oxygen under the corresponding conditions

Ethylene and Propylene

Both ethylene and propylene burn in nitrous oxide with an enlarged flame having an intensely luminous central zone, they also form with nitrous oxide highly explosive gas mixtures The ignition-points of these gases were determined in the same way by bringing them into the concentric-tube apparatus filled with nitrous oxide In Tables II and III are given the average of the readings made at different pressures compared with those found for the same gases in oxygen under the same conditions

Table II —*Ignition-points of Ethylene in Nitrous Oxide and in Oxygen at Different Pressures*

Pressure	760 mm		550 mm		400 mm		250 mm		150 mm	
Atmosphere	N_2O	O_2	N_2O	O_2	N_2O	O	N_2O	O_2	N_2O	O_2
Lag—										
½ in	592°	604°	605°	624°	605°	660°	592°	650°	578°	617°
1 in	572	593	584	613	584	646	572	634	560	600
2 in	529	584	554	601	548	625	—	614	—	580

The crucial pressure for ethylene in nitrous oxide is seen to be about 500 mm. , at this pressure ethylene ignites within half a second at 605° C At the atmospheric pressure ethylene ignites rapidly at 592° C , which is only 14° C below the ignition-point in oxygen , but when the mingling gases are in contact with a heated surface the difference between the ignition-points is more marked Under the same conditions ethylene ignites at a lower temperature in nitrous oxide than in oxygen but at low pressures the ethylene fails to ignite when the lag exceeds one second

The ethylene used in these experiments was mainly that prepared and condensed in steel cylinders by the British Oxygen Company This gas contains a very small amount of impurity (chiefly nitrogen), but gave the same ignition-points as that prepared and purified in the laboratory

The propylene used was prepared in the laboratory both from normal propyl and from isopropyl alcohol In each case ethers were formed in considerable quantity, and had to be condensed and washed from the gas When the propylene was tested in the concentric-tube apparatus it ignited at ordinary where a fringe from the quadriceps tendon and attached periosteum may hang down between the fragments

The Distinction between Non-union and Delayed Union

Before undertaking an operation it is desirable to be sure that one is dealing with true non-union, not merely *delayed union* This distinction is not merely one of time, for in the absence of mechanical hindrances a fracture which has been inert for months may suddenly unite

In the doubtful case, after all the causes, local and general, referred to above have been excluded, and measures have been taken to raise the general health of the body, it is wise to apply local stimulation to the bone-ends by such means as heavy massage, use of the limb, with just sufficient splinting to guard against gross displacement—e g, for the lower limb walking in the Thomas calliper—and finally, hammering the bone-ends through the soft parts, as recommended by Hugh Owen Thomas It may also be useful to apply intermittent congestion by rubber bandages round the limb above and below the fracture Progress should be controlled every few weeks by X ray examination, when it should be remembered that, in the early stages of repair, callus which will give ultimate good union may contain too little calcium for it to be easily demonstrable on the skiagram The progress shown by X rays will appear much slower than it is actually, so that most reliance must be placed on clinical signs

Conversely, a fracture may appear in the skiagram to be united, when there is merely interlock of irregular bone-ends, which will be found at operation to be sealed off from each other by a thin sheet of fibrous tissue Such a fracture may give good function for a time, but this tends to diminish, while the limb tires more and more easily, and the bone becomes the seat of a chronic ache It is sometimes hard to distinguish the deep tenderness in such a case from the tenderness of active callus, one of its most valuable signs If mobility of the fractured ends persists with a total absence of tenderness, a true non-union can be diagnosed with almost complete certainty

These points in diagnosis have been stressed at some length, because, unless they are appreciated, many unnecessary and some unsuccessful operations will be performed A bone operation is never to be undertaken lightly, and certainly not unless strict asepsis can be guaranteed at the operation and efficient nursing afterwards This does not mean that such operations cannot be done in the most remote highland cottage, since asepsis depends on the surgeon and the nurses more than on external conditions, nevertheless, the surgeon for whom conditions are not favourable will be wise to give his border-line cases the benefit of conservative measures first for a considerable time

Operative Technique

It will be clear from what has already been said that the first essential to the success of the operation is a radical clearing of the bone-ends from scar tissue and free opening up of the medullary cavity, whenever possible, by cutting away all the sclerosed bone from each end Where sclerosis extends too far in each direction to allow of this, multiple tunnels may be drilled up the shaft till free bleeding occurs from them In a fracture of the humerus, or of both bones of the forearm, it is better to shorten the limb by sacrificing a little of the length of the bone in order to get vascular bone end to end, rather than to leave in contact two pieces that look like ivory, for these would never unite In the lower limb sacrifice of length is not lightly to be undertaken, but occasionally amounts up to 1 inch are justifiable In the forearm, if the radius alone is ununited, as it is the key bone for the function of the hand, it is often justifiable to shorten the ulna, so as to allow end-to-end union, rather than to use a bridge graft, more especially if there is extensive scarring of the soft parts, which would not provide a suitable bed for a graft

The use of *mechanical accessories* as a further stage in the operation is a complicated subject, though the principles involved are simple If it is remembered that a bone is a living tissue, not an inert strut, then it will be recognised that many of the devices of the carpenter and the blacksmith, which may be admirable for the repair of wood and metal, may yet be quite ineffective for human bone, conversely, a type of joinery which would disgrace a carpenter may give excellent surgical results Thus all forms of metal attachments have a tendency to cause atrophy of the bone in their neighbourhood, so that, however firm their hold at the operation, unless they are rapidly supported by living callus between the bone-ends they will be unable to resist deforming forces such as the body-weight If they are applied so as to lie in, or just on the bone-ends, they may even inhibit the production of this essential callus, and so defeat the very object for which they were used It is well known that the association of the slightest infection with such foreign material has a most injurious effect on tissues which might be able to cope with the infection alone No surgeon can guarantee that in any fracture which has been compound his manipulations may not light up an infection, which had become quiescent, for such infections may remain latent for years in bone Although the preliminary injection of antitoxin—e g, antistreptococcal and antitetanic, in these cases is desirable, it cannot be made specific for every possible infection For all these reasons metal should be used as rarely as possible, and should be removed as soon as its work is done this latter recommendation is now agreed to even by most of the enthusiasts for plating In the case of small fragments like the internal condyle of the humerus, which are difficult to keep in place after reduction, Stiles's method is useful—i e. the use of a long nail, passed right through the skin, kept in sterile dressings, and removed at the end of three weeks

Even autogenous bone-grafts are not exempt from some of the objections referred to in connexion with metal plates Modern research on this subject suggests that bone-grafts act chiefly as a scaffold for the osteoblasts of the body to travel along in laying their new bricks, the graft being progressively removed by a process too subtle to be followed in skiagrams. Therefore a very dense graft, such as one from the crest of the tibia, acts almost as a foreign body and one difficult to remove, on the other hand, if osteoclasis happens to outrun osteogenesis, even the heaviest graft may break just at the site of the original non-union which it was supposed to cure It is true that union may occur in such a broken graft, but the callus is seldom abundant For these reasons it must not be thought that the use of a metal plate or a bone-graft eliminates the need for a certain amount of external splinting and the usual measures of after-treatment, such as massage and controlled movements Some fractured bones can be trusted without a splint, even in the absence of a graft or plate, but those which require support normally will require it equally after a plastic operation

For the fixation of the graft itself usually strong catgut sutures (Nos 2 or 3 iodine-tannic catgut) through the periosteal sheath are sufficient Sometimes it is possible to wedge the graft so firmly into a gutter in the fractured bone that no sutures at all are required The intramedullary peg-graft has been given up almost entirely, even by those who were at one time its enthusiastic advocates, because it was found not to allow sufficient callus formation owing to blockage of the vascular medullary cavity

Briefly summarised, the principles of treatment common to all cases are —

1 Exclusion of all the causes of non-union, due to the *general state* of the patient's health, with appropriate treatment for any that are found

2 Exclusion of all local causes due to pathological conditions of the bone, such as *tumours* and *cysts* or if these are found, radical removal with restitution of the bone by some form of bone-grafting operation.

3 Careful and thorough treatment of any local *sepsis* in compound fractures with early removal of definite sequestra after careful study of radiographs in two planes, so that none may be missed

4 Open operation when some *mechanical obstruction* to union is known to exist, or after a reasonable time has been given to conservative measures, when serial X rays show no evidence of callus and clinical examination confirms the diagnosis At the operation free opening up of the medullary cavity each end securing wide surfaces of contact of raw bone if necessary with the assistance of an autogenous graft

5 Adequate external *splintage* after operation and *physiotherapy* at an early date

Surgeon, Bath, Somerset, and Wilts Central
Children's Orthopædic Hospital

equally valuable, is one part of permanganate of potash to five thousand parts of warm water.

Masks.—The temporary use of masks by those who are attending patients may be occasionally desirable, but for general purposes they are not recommended. By hindering the free circulation of air through the nasal passages they cause turgescence and œdema of the mucosæ and possibly increase the liability of infection.

Vaccines.—No vaccine is yet available which will ward off an attack of the disease, but there is evidence that the use of suitable vaccines may protect against complications by secondary infection, especially those of the pneumococcus and streptococcus. No drug has been proved to exert any specific influence as a preventive of influenza.

Needless Exposure.—Most people are able to avoid at least some occasions of forming part of a crowd or assembly without prejudice to their necessary occupations. To keep away from all places of public resort or social gathering will increase the chances of any citizen of remaining immune.

Precautions when Attacked.—The first symptoms are well-known, and to continue at work after they appear is bad for the patient and may be dangerous to others. Workers obviously ill should at once be sent or taken home. Where influenza is prevalent no person should in any way be penalised for staying away from work for even a slight attack of influenza or any form of feverish cold. On the contrary, he should be expected or required to do so. At the first feeling of illness or rise of temperature the patient should go to bed, keep warm, and seek medical treatment. The doctor, if called in at once, has the opportunity of giving advice or treatment which may forestall the more dangerous complications. Relapses and complications are much less likely to occur if the patient goes to bed at once and remains there *for two or three days after all* fever has gone. Much harm may be done by getting about too early, and many evil consequences are due to *chill and over-exertion* during convalescence.

The early stages of the attack are the most infectious, but the infection may persist throughout the illness, and the patient should be isolated at least until the temperature is normal. If he *cannot* be given a separate room, the head of the bed should, if possible, be screened off. The virus of influenza is easily destroyed and extensive disinfection is unnecessary. All expectoration should be received in an antiseptic solution, and discarded handkerchiefs should be immediately placed in disinfectant or, if of paper, burned. Those attending a patient should avoid inhaling his breath, particularly when he is coughing, sneezing, or talking. The patient himself should turn aside at these times and hold a handkerchief before his mouth. The nurse's hands should be washed at once after contact with the patient or the discharges from his nose and throat.

MEASURES FOR THE LOCAL AUTHORITIES

The imposing of quarantine on persons arriving from abroad has been dismissed as impracticable.

Education.—Most important work can be done by the health authorities by means of leaflets, posters, notices in the press, lectures in the schools, &c., to teach the public the facts about influenza and its gravity and the methods by which they may prevent infection and look after themselves if attacked. No less important is full and exact information about the local facilities which have been provided in the district. Every person should know how to apply for nursing assistance, the special arrangements for the provision of medical attendance, how a household stricken by influenza can apply for “home help”; the positions of public kitchens, creches, &c., the hospitals and ambulance services available for sudden or severe cases.

Notification.—The Ministry has decided not to make influenza a compulsorily notifiable disease. Notification is not likely to improve preventive measures nor to help local authorities to attend to those cases or households which most need assistance. The statistical value of notification is compromised both by the large number of cases not seen by a doctor at all and by the uncertainty with which the term “influenza” is used. Many local authorities will, however, find it useful to make an arrangement with practitioners in their district to notify all cases where nursing, home-help, or institutional treatment is required. Otherwise health visitors may be used to report such cases. Acute influenzal pneumonia is, of course, already notifiable in all districts of England and Wales under the Public Health Regulations.

Protection of Doctors and Nurses.—Authorities do not fully realise the importance of protecting those in attendance on the patient. One of the most tragic features in the last pandemic was the high mortality among hospital staffs, some of which might have been prevented by observing the ordinary precautions applicable to all acute infectious diseases.

Closure of Schools.—In rural and small urban districts where the children have few opportunities of coming in contact with each other outside the school this measure may be useful. It has not much value in densely-populated towns. When day-schools are closed Sunday-schools should be closed as well. Children showing symptoms of influenza should be excluded from school until their heart and lungs have been carefully examined to eliminate latent complications and sequelæ.

Public Places of Entertainment.—The Emergency Regulations issued by the Local Government Board in 1918 gave local authorities power to compel the proprietors of all places of public entertainment to exclude from their performances children of school age, and to provide intervals for the sufficient ventilation and perflation of the building. These regulations were withdrawn in May, 1919, and no sufficient justification has yet been advanced for their reissue.

Other Centres of Overcrowding.—The overcrowding of trains and trams was largely responsible for the spread of the disease in 1918. Permanent through ventilation should be generally advocated and adopted.

Disinfection.—The routine disinfection of premises and articles after use by influenza patients is not called for, but a thorough washing and cleansing of rooms and their contents and of washable articles, bedding, or apparel is desirable. The practice of spraying halls and places of public resort with disinfectants is of little use, and tends to create a false sense of security.

ORGANISATION OF LOCAL MEDICAL SERVICES

Domiciliary Medical and Nursing Service.—In serious epidemics where it is difficult to ensure that every case as it arises shall have early and adequate professional treatment it is often useful to form a “pool” of unattached medical men whose services can be placed at the disposal of practitioners as required. In larger areas part of such a pool may be formed by the health authority's own medical staff. Shortage of nurses is often a more serious problem, but may be combated by subdividing the district into small areas and using one or more nurses in each area as a nucleus for a body of voluntary helpers. Some local authorities in extreme emergencies may have to liberate their maternity and child welfare workers and health visitors for this purpose. Any scheme should include the cooperation of the local district nursing association. Many kinds of home assistance can be arranged with the help of the health visitors, and certain districts may find it desirable to establish emergency kitchens for supplying food to affected households and to form creches for children whose parents are unable to look after them.

Provision of Institutional Treatment.—The local authorities will often find it helpful to use one or more wards of the isolation hospital to supplement the general hospitals and Poor-law infirmaries pressures both in oxygen and in nitrous oxide at a lower temperature than ethylene under the same conditions, but at low pressures the ignitions of propylene in nitrous oxide were sometimes found higher than those of ethylene The ignitions of propylene in nitrous oxide were always lower than in oxygen under the same conditions (Table III)

TABLE III —*Ignition-points of Propylene in Nitrous Oxide and in Oxygen at Different Pressures*

Pressure	760 mm		550 mm		400 mm		250 mm		150 mm	
Atmosphere	N_2O	O_2	N_2O	O_2	N_2O	O_2	N_2O	O_2	N_2O	O_2
Lag—										
½ in	564°	586°	580°	605°	589°	623°	591°	620°	587°	608°
1 in	554	574	569	594	575	608	579	605	575	595

The crucial pressure for propylene is some 200 mm lower than that of ethylene, otherwise the ignitions are governed by the same general rule

The results of these experiments show that Davy's generalisation does not apply to gas mixtures Hydrogen, ethylene, and propylene (and presumably other gases) mixed with nitrous oxide form explosive mixtures more readily ignitable by heat than similar mixtures with oxygen.

INFLUENZA

MEMORANDUM BY MINISTRY OF HEALTH

IN 1919, when the last serious pandemic of influenza swept the world, and 112,000 deaths occurred in England and Wales alone, the Ministry of Health issued to all local sanitary authorities and medical officers of health a memorandum[1] summarising the latest available experience in dealing with the disease In view of the prevalence of influenza in certain countries abroad, the Minister has now circulated a revised edition of this Memorandum [2] The information it contains, although it will not add greatly to the knowledge of most practitioners, has been carefully compiled from reliable sources and forms a useful résumé of our present knowledge of ætiology, prophylaxis, and treatment

SUMMARY OF THE MEMORANDUM

The following is a summary of the Ministry's pronouncement —

Influenza, if uncomplicated, is short and sharp, and recovery is rapid The deaths that it causes are usually due to pulmonary or cardiac complications, and in severe and fatal cases it is generally shown that some organism not specifically associated with influenza has obtained a foothold, probably because of the lowering of the resistance by the influenza virus The commonest complication, especially in the autumn and the spring, is pneumonia The infection passes very rapidly through a community and will spread over a large town in a few weeks Enough is not yet known about the epidemiology to enable a central authority to give timely warning of a serious outbreak Epidemic periods usually end by the waves of prevalence becoming less intense and more widely spread The symptoms of the later cases become more and more confused with those of ordinary catarrhs, which come to be regarded as influenza on comparatively slight evidence, so that the term "acute epidemic influenza" becomes forgotten, and "influenza" is applied to all kinds of indeterminate febrile conditions This tendency makes it so difficult to procure continuous records of the occurrence of true influenza that it is impossible to forecast with any confidence the arrival of a new epidemic wave

Ætiology

Although research is being keenly prosecuted in many countries the nature of the virus of influenza is still unknown No specific form of treatment or prophylaxis exists, nor is it possible to distinguish surely between the autumn and winter outbreaks of "influenzal catarrh" and the pandemic form of 1918 and 1890 On the bacteriological question opinion is still divided between the adherents of Pfeiffer's theory and those who believe that the true causal agent is some other organism, probably a filter-passer, like that which Olitsky and Gates have called *Bacterium pneumosintes* Pfeiffer admits that he cannot explain the remarkable increase in the virulence of the bacillus which must be assumed to occur at the onset of an epidemic, nor has he succeeded in satisfactorily associating his bacillus with the disease by serological methods Although his theory leaves so much to be desired the opposite school have probably a long task before them if they are to accumulate sufficient evidence to win the day

The facts concerning the spread of the disease are, however, fairly well established Infection is conveyed from the sick to the healthy by the secretions of the respiratory surfaces, which are transmitted through the air as a fine spray in coughing, sneezing, and even in loud talking There is a special danger of receiving a massive infection from a person talking loudly within four feet, or coughing or sneezing, without interposing any screen, within ten feet A lesser danger occurs when finer infective particles are carried longer distances by draughts or convection currents The channels of reception are normally the nose and throat, and sometimes the eyes Only a brief exposure is necessary in order to contract infection and the closer the contact the more readily is the virus transmitted It is therefore vitally important to avoid overcrowding of every kind in places of public resort, public conveyances, factories, camps, living rooms, and dormitories When many persons are collected in the same sleeping quarters there is an additional danger of the spread of secondary infections Infection can also be carried to the mouth by a hand soiled with the respiratory secretion of an infected person, or by the use of a soiled handkerchief Temporary overcrowding in trams, trains, omnibuses, and places of entertainment is a more important factor in the spread of an epidemic than is overcrowding in the home, no regular increase of the attack rate has been proved to follow an increase in the number of persons per room in urban tenements.

The period of incubation is about 48 hours, or perhaps somewhat less There is evidence that an attack of influenza may confer some degree of immunity for a few months, but this is by no means invariable

MEASURES OF PERSONAL PROTECTION

In the absence of specific prophylaxis, most members of the community who continue their ordinary work must expect to be exposed to infection, but every citizen can do a great deal both to safeguard himself and to avoid infecting others

Ventilation —Well-ventilated, airy rooms minimise risk by promoting physical well-being Fresh air dilutes and dissipates infective material Draughts and chilling of the body-surface should be avoided

Nutrition —Good nourishing food is desirable. A Memorandum issued in 1919 by the Royal College of Physicians states that alcohol in excess invites disaster, and that everyone should maintain unaltered within the limits of moderation the habits which he has found to keep him in the best health Cod-liver oil raises the immunity

Gargling —The importance of gargling should not be overrated, it is chiefly useful on returning home after exposure to infection in a crowd or from an infected person For gargling one of the most effective antiseptics, and a palatable one, is a full tablespoonful of compound glycerine of thymol to a tumblerful of warm water Cheaper, and perhaps were, at this time, occupied, and the parents were told to keep the child isolated It was later found that the boy, though still in the peeling stage, had been sent on an errand, the parents pleading ignorance of the fact that he was still in an infectious state

Silver Poisoning

A verdict of death from pneumonia, with silver poisoning as a contributory factor, was recorded on Jan 10th at an inquest at West Bromwich upon the body of a silver polisher The report of the case in the *West Bromwich Free Press* revealed some difference of opinion among the medical witnesses Dr Downie, resident physician of Hallam Hospital, said that the post-mortem examination showed the cause of death to be meningitis, of which no mention was made on the death certificate, which gave the causes as pneumonia and heart failure He found that the skin of the deceased's neck and face was pigmented and of a bluish colour In reply to the coroner, he is reported to have said that he was of opinion that there was no such thing as silver poisoning, and that the presence of silver in the body would have no harmful effect Dr Mackenzie, of Birmingham University, gave evidence that he had found a silver deposit in certain organs of the body This, he considered, would lower the patient's vitality to such a degree that no insurance company would accept him under a policy He regarded silver poisoning as a contributory cause of death, and denied that the matter was one of speculation The deceased's private medical practitioner, Dr Moore, also expressed the opinion that the patient had suffered from silver poisoning The assistant works manager of the firm which had employed the man said that the firm used only pure silver He stated that he had never heard of silver poisoning, nor had any other employee suffered from pigmentation or showed any bluish colour In recording the verdict as mentioned above, the coroner remarked that it was obvious that cases of silver poisoning were rare, and that the deceased was evidently susceptible. He had been taken ill last May and was in hospital till July, when he was discharged and went to recuperate at Llandudno, his health, however, did not greatly improve, and in December he was again ordered to hospital, suffering from pleurisy and pneumonia In the coroner's opinion the presence of silver deposits accounted for the abnormal period of continuing debility

Disposal of Sewage.

An important action was lately brought by the Attorney-General, on the relation of the corporation of Bradford, asking the Court of Chancery to restrain a wool-combing company from causing or suffering sewage from its works which would interfere with the treatment or utilisation of the city's sewage to flow or pass into the municipal sewers or drains Bradford's problem is peculiar As the centre of the worsted industry it has to cope with a large proportion of the wool-combing and wool-washing of the country Wool-combing operations produce immense quantities of suds, wool-washing removes from the fleeces, with the aid of alkaline substances, a mass of lanoline fat which does not float upon the surface of an effluent and therefore cannot be skimmed off Under a local Act of 1897 the city took power to deal with this refuse The Act imposed penalties upon firms which caused the refuse to enter the sewers, but, by a not unusual compromise, exempted the manufacturers if they had done their best to prevent it and had erected suitable apparatus for the purpose The difficulty of erecting apparatus has been the want of space in many instances The corporation of Bradford has made agreements with several manufacturers and offered to make a similar agreement with the company against which action is now being taken This company, however, asserted its right to throw alkaline matters into the municipal sewers—an assertion which the corporation was bound to contest On the corporation's behalf it was estimated that the defendant company sent 78,000 000 gallons of untreated refuse into the sewers every year, and that the treatment of this volume with sulphuric acid involved an additional amount of 55 tons of acid per week. If the defendants succeeded in their contention, and if other wool-combers also sent their refuse into the sewers untreated, the municipal drainage system would break down, and the sewage purification works (on which 2½ millions had been spent) would be utterly insufficient for the discharge of the corporation's statutory duties After hearing evidence on behalf of the city, the defendant company consented to give an undertaking in the terms of the statement of claim, and submitted to an order to pay the costs of the action There will be an inquiry as to damages The defendant company admitted that it could not claim a prescriptive right to turn its waste into the sewers The case illustrates the modern difficulties of large-scale sewage disposal in trade centres, and shows the kind of problem which the advocates of clean rivers sometimes have to solve

---

IRELAND

(FROM OUR OWN CORRESPONDENT)

Appointment of County Medical Officers of Health

THE Department of Local Government and Public Health is meeting with considerable opposition from the local authorities throughout the Irish Free State in regard to the appointment of county medical officers of health

The appointment is compulsory under the Local Government Act (1925), but most of the county health boards are pleading one excuse or another in order to postpone action In face of this position the Department has taken an unusual and courageous step in making a propagandist communication to the Press on the subject of expenditure on public health Last week Mr E P McCarron, the Secretary of the Department, who was accompanied by Dr E F Stephenson, Chief Medical Officer, received representatives of the Press, and told them that the public health organisation was definitely behind modern requirements, owing largely to the fact that the expert local health officers were primarily employed in treating disease

The relatively backward condition of hygienic control in Ireland had placed the country at a commercial disadvantage with such rivals as Denmark and while not as important as the health of the people, the trade aspect of public health administration was important The main essentials in public health administration were (1) Sanitary areas of adequate extent, and (2) trained whole-time health officers to control the sanitary inspectors and to administer the laws and regulations impartially Infection and disease had little relation to arbitrary administrative boundaries, and it was beyond dispute that the best results in the prevention of human suffering and death were achieved in large areas of local control

Experience had shown that however competent a part-time medical practitioner might personally be, he frequently suffered from certain unavoidable disabilities in his capacity as a medical officer of health He was individualistic rather than communal in outlook, and his public duties conflicted with his interest as a private practitioner and often brought him into collision with his fellow practitioners.

The ophthalmic experts of the Department, said Mr McCarron, stated that 690 pensions in the Saorstat were paid to persons whose blindness was attributable to preventable causes The wreckage of human beings caused by crippledom, which was largely preventable, was one of many other unnecessary burdens of the ratepayer, and economy secured at the expense of the people's health was prodigal waste of a national asset Considering that the actual cost of this fundamental service in most country areas was but a fraction of 1*d* in the £, it was difficult to understand the hesitancy of local authorities in making the appointments

They should take care in selecting cases for removal to hospital Patients with pulmonary complications bear removal badly, and should only be moved with the concurrence and supervision of their medical attendant Patients in hospital should be isolated by screening or otherwise, and ambulance and nursing attendants should observe all the precautions proper to the handling of an acutely infectious respiratory disease By the establishment of emergency hospitals in schools, halls, and large unoccupied private houses, the supply of doctors and nurses, particularly the latter, may be considerably economised

THE VITAL STATISTICS OF NEW YORK STATE

New York State has a population of ten and three-quarter millions, of which more than one-half lives in New York City itself It has a complete system of registration of births and deaths, and its experience, for many reasons, is more interesting than that of any other community with a corresponding population

Birth-rates —One reason for this is the mixed character of its population, which is largely foreign born The fertility among different sections of the population is fully set out Thus the average number of children born to those women of the several racial stocks who became mothers in 1923 was for native white women, 2 8, for natives of Poland, 5 0, of Hungary, 4 8, of Italy, 4 6; of Great Britain, 2 9 But these figures do not necessarily relate to completed families and may not be strictly comparable The contrast as to medical attendance at birth between New York State and England is striking In the latter a majority of births are attended by midwives, in New York State there is a medical attendant in over 90 per cent of the total confinements, the lowest proportion being 53 per cent for Poles and 61 per cent for Hungarians

Death-rates —The total death-rate for the State was 13 1 per 1000, a reduction of 28 per cent as compared with 1900 The reduction was equal to one-half at ages under 9, to one-third between 10 and 39 years The success of organised public health work is especially indicated by the reduction of the diarrhœal death-rate (under 2) from 124 to 27, of diphtheria from 45 4 to 9 4, and of typhoid fever from 26 7 to 2 9 per 100,000 of population In a series of tables rates are given which will enable the student of statistics to compare deaths and causes of deaths for each age-period with those of other countries At all ages in the aggregate, diseases of the heart, pneumonia (all forms), cancer, and tuberculosis headed the list in seriousness, chronic nephritis and accident coming next in sequence In a striking table it is seen that at ages 4–5, 5–9, 10–14, accidents hold first place as a cause of death for both sexes, and that for males they occupy the same place at ages 15–19 At ages 2–4 pneumonia is the chief cause of death, At ages 15–44 tuberculosis holds this place, and it is only after the age of 45 that the congeries of end-results called diseases of the heart take the first place in determining death

Infant and Maternal Mortality —The infant mortality-rate 72 per 1000, was the lowest on record It varied from 160 among negroes, 103 in Canadians, and 98 in Poles, to 43 in infants of Russian mothers, who in New York State are mainly Jewish The number of deaths from diseases of the puerperal state per 1000 births was 5 3 There is a remarkable difference between New York City and the rest of the State in puerperal septicæmia, the death-rate being 8 5 per 10,000 births in the City and 18 7 in the rest of the State There is little difference between the two in respect of all other puerperal causes of death

Tuberculosis —Not only has the death-rate from tuberculosis declined to a remarkable extent, but now the rate for this disease (all forms) is lower in New York, being 95 7 per 100 000 of population, as compared with 100 8 for the rest of the State At nearly all ages male was higher than female mortality from this disease In New York City at ages 45–54 the male was two and a half times the female rate at ages 55–64 it was three times, and after the age of 65 more than twice the mortality among females

Cancer —The registered death-rate from this disease was 113 9 per 100,000, representing an increase of 38 per cent since 1910 In the same interval the registered mortality from cancer increased by 53 per cent in Buffalo, by 67 per cent in Schenectady, and by only 13 per cent in Rochester and 16 per cent in Syracuse, and it appears reasonable to assume that these variations are due more to differences in certification of death than in incidence of disease

Bronchitis and Pneumonia —One of the most interesting differences between American and English statistics is the extent to which in the former pneumonia exceeds bronchitis as a registered cause of death In 1913–17 in New York State bronchitis was the cause of an average of 18 5 deaths per 100,000 of population, while pneumonia caused 172 per 100,000. The pneumonia death-rate was practically equal in New York City and in the rest of the State and there was but little difference between the rural and the urban death-rate from pneumonia

Alcoholism —In view of the discrepant evidence as to the results of prohibition the following figures are of interest, relating as they do to one of the "wettest" states in the Union

Alcoholism *Death-rate per 100,000 Population, New York State*

1914	1915	1916	1917	1918	1919	1920	1921	1922	1923
9 2	7 9	10 1	8 3	3 8	2 6	1 4	1 7	3 5	5 5

Since 1923 there has probably been some further increase With these may be contrasted the figures for cirrhosis of the liver

Years	Rate per 100,000	Years	Rate per 100,000
Average of—			
1913–17	14 7	1922	7 0
1918–22	7 8	1923	6 2

In this instance the death-rate, unlike that from alcoholism, appears to be still declining

Deaths in Asylums —It is noteworthy that in one of 22 deaths of adults "mental darkness preceded physical death" These deaths include only those occurring in public institutions

MEDICINE AND THE LAW

Small-pox at Sheffield—Parents Fined

A FATHER and mother were fined £2 10*s* each at Sheffield on Jan 13th for exposing their children when suffering from small-pox the father being further fined £1 for not notifying the cases Dr F E Wynne medical officer of health, said that the children showed signs of having had small-pox for five weeks Three children were infected, it appeared that the eldest girl was working in a place where several others were employed, a room in the house was used for meetings, and one of the children admitted visitors and conducted them to this room, a son was sent by his mother to take the father s dinner to his place of work, even after she had been informed that the boy was suffering from small-pox The mother said she thought the children had chicken-pox though they had suffered from that only six months before Other evidence indicated that she had been reluctant to part with her children to the hospital, though once they were removed there, she was full of praise for the officials

On the same day, at Sheffield, two other parents were fined 5*s* each for permitting their son while suffering from scarlet fever, to be exposed without proper precautions against spreading the disease The case had been notified early in November An inspector, who visited the house, found eight persons living in it, and arranged to remove the boy to hospital Apparently all the scarlet fever beds at the hospital slowly into a bucket The fluid measured 40 pints and was quite clear

It was my intention, then, to give her spinal analgesia, but she was so deeply narcotised that I extended my incision considerably without even further local analgesia and started to strip it To my surprise I found I was not in the abdominal cavity The cyst was extraperitoneal and all the abdominal contents were packed away into the upper part of the abdomen The cyst wall was gradually stripped off, no pedicle was found. A large drainage-tube was pushed through close to the centre of the crest of the ilium and the abdominal wall sutured Free sanious oozing took place through the tube which was shortened day by day and removed on the sixth The intestines gradually came back into their normal position The woman made an uneventful recovery and went home on the seventeenth day.

This was I suppose a pelvic cyst which gradually stripped up the peritoneum as it extended upwards I should be glad to hear any suggestion as to its possible origin To me it was remarkable to be able to perform an extensive operation under a single injection of morphia and hyoscine

I am Sir yours faithfully,
F J W Porter
Karachi, Dec 30th, 1926 Major, R A M C (retd)

PULMONARY EMBOLISM FOLLOWING OPERATION

To the Editor of The Lancet

Sir,—Dr W A. Lister's statistical study of post-operative pulmonary embolism (The Lancet Jan 15th p 111), is a most valuable contribution to our very limited knowledge of this difficult but most important problem I am gratified to find that Dr Lister's figures tend to confirm several of the conclusions [1] which I arrived at in 1921, but which are still not generally admitted Perhaps the most important of these is that sepsis is not a factor of importance. A great many surgeons still believe that sepsis in some form is the main factor in the production of thrombosis after operation These figures, which are much more complete than any hitherto produced, give very strong evidence that sepsis cannot be considered an important factor

Dr Lister also confirms my conclusion that venous stasis in the large venous trunks of the abdomen is the main factor, and his argument that this stasis tends to be produced as a secondary result of an abdominal incision is sound His contention is that the pain caused by any movement of the abdominal wall tends to hamper the action of the diaphragm which is necessary for maintaining the flow of blood through the great abdominal veins I suggest that the presence of a tight bandage round the abdomen is also a factor of importance in hampering the excursions of the abdominal wall

The difficulty in accepting this theory of venous stasis is, as I pointed out five years ago, that experimental evidence shows that venous stasis alone cannot produce intravascular clotting The ligature of a vein in two places, so as to produce complete stasis of the contained blood does not result in the formation of a thrombus within that vein, even in two weeks Some other factor must therefore be present before stasis is able to produce intravascular clotting I suggested that a substance present in all tissues but normally not present in blood—namely thrombokinase, is the factor This substance is liberated whenever tissues are injured, as by an operation or fracture of a bone, or even normal childbirth If stasis in the veins coincides with the liberation of thrombokinase owing to an injury, then both the factors necessary for the production of a thrombus are present and a clot may form

Dr Lister says in his article, "if the liberation of thrombokinase predisposed to the condition, then such operations as Halstead's amputation of the breast or nephrectomy should show a high rate of incidence," but this is not so, as in these operations, although thrombokinase is liberated as it is in all operations the other factor stasis of the blood in the large veins is not present or at least not in the same degree as when an abdominal incision has been made As proving the importance of this substance, thrombokinase, as a factor in the formation of clotting there is an old but interesting experiment If blood is drawn off from the centre of a large blood-vessel by means of a needle and syringe great care being exercised to prevent any possible contamination of the blood with any substance not normally present in the blood itself, the blood so obtained will not clot at all It will in fact go bad and decompose eventually without clotting

Dr Lister's paper has I believe, helped very much in clearing up some of the debatable points in the difficult problem of post-operative thrombosis and embolism and demonstrates how useful the statistical methods can be when properly carried out Our knowledge is still very deficient, and further light is badly wanted on the physiological and experimental side of the problem, especially in relation to the exact mechanism of intravascular clotting and a more exact knowledge of the physiology of the condition might, and probably would, go a long way to solve the surgeon's problem of how to prevent his patients getting pulmonary embolism after operations It is a subject for regret that in these days the physiologist and the surgeon are not in closer touch In the present state of our knowledge I doubt if there are any means known to us of either preventing, or dealing with the condition which are of any value Early movement and massage are doubtful expedients, as I believe that quite often the clot forms either on the operating table, or before the patient is round from the anæsthetic and under such circumstances these measures will do harm rather than good It is full time that we did know how to prevent the condition as it is accountable for quite a considerable number of disasters, and the general impression among surgeons is that it is becoming more frequent as a complication of abdominal operations

I am, Sir, yours faithfully,
J P Lockhart-Mummery, F R C S.

OBESITY AND TEMPERAMENT

To the Editor of The Lancet

Sir —After reading of the Italian Premier's alleged dislike for obese people, I thought it might be of interest to analyse the temperamental characteristics displayed by the fat and the lean as met with in general practice Though there may be exceptions the metabolic processes in the adipose are usually slower than in the lean, and this probably accounts for the good nature and easy going character usually displayed by fat people The slim figure demanded by modern fashion has led to innumerable cases of dieting among obese women, and I have noted how a previously contented, cheerful and placid individual has on attaining a marked reduction in her weight, become irritable, sullen, and often definitely bad tempered I admit that with moderate reduction in weight in cases where the obesity has been marked activity of both body and mind is usually increased but if the reducing process has been carried too far, pronounced lassitude with nervous irritability occurs Like the Cæsar who preferred fat men around him complaining that "Yon Cassius hath a lean and hungry look" I think most of us have learnt to expect and discover geniality and sociability among those with a leaning to adiposity.

I am, Sir, yours faithfully,
Alfred A Masser M B , Ch.B.

BLOOD PRESSURE IN INFLUENZA

To the Editor of THE LANCET

SIR,—While the present outbreak of influenza is still in progress may I draw attention to a clinical phenomenon which I believe to be of both diagnostic and prognostic importance I refer to the fall of blood pressure which is almost always to be found in cases of any severity My attention was first drawn to this sign during the epidemic at the end of the war, when I referred to it in a report to the Medical Research Council (Special Report Series, No 36) I then recorded the average systolic blood pressure of a ward of 35 soldiers as being only 93 mm Hg It is possible that at that time other factors, such as fatigue, contributed to the low value, but I find the same now among private and hospital patients, in whom a fall of 10 to 20 mm seems to be common.

The low systolic pressure undoubtedly indicates a toxic condition of the cardiovascular system, and may be in part responsible for the throbbing character of the frontal headache, and for other symptoms I have heard of and seen several cases who, on sitting up in bed suddenly have fainted or become so dizzy as to have to lie down again at once Such patients have low systolic pressure The pressure seems to be at its lowest at about the fourth or fifth day, which is just when in so many cases the fever has passed and the patient wants to get up and see to his affairs No patient should be allowed to leave his bed in this condition During convalescence the blood pressure rises slowly to its normal, but may take a week or two to attain it Much of the feeling of depression and lassitude after influenza is associated with this condition

From my observations on the morbid anatomy of this disease during 1918-1919 (over 170 post mortems) I found the heart muscle to be constantly affected Hyaline degeneration of all the muscular tissue of the body occurs rapidly in influenza, and its effect upon the heart muscle is seen in the systolic blood pressure I think it probable that the toxin of influenza affects the suprarenal bodies also, and through them produces a lowered pressure, but I think the chief method of its production is cardiac

No one would knowingly allow a patient whose heart muscle is in this condition to get up, take a hot bath, or go out, but would keep him in bed and administer tonics until the period of risk is passed I would like to draw attention to the systolic blood pressure as one of the few sure guides in allowing a patient suffering from influenza to get about and as an inclination for further tonic or convalescent treatment. I am, Sir, yours faithfully,

T H G. SHORE

Harley-street, W 1, Jan 24th, 1927

IS THE PRESENT EPIDEMIC OF INFLUENZA DUE TO A STREPTOCOCCUS?

To the Editor of THE LANCET

SIR,—Towards the end of last century the influenza bacillus, or Pfeiffer's bacillus, was incriminated as the cause of influenza, and the ætiology of this important disease was hardly even further questioned until the occurrence of the pan-epidemic of 1918 Investigations made into the ætiology of this last great epidemic began to show that it was very doubtful if Pfeiffer's bacillus was after all the true cause of the malady, and many bacteriologists inclined towards the belief that the disease was due to some strange unknown, minute, filter-passing virus The researches of Olitsky and Gates at the Rockefeller Institute revealed the presence in influenza cases of a minute Gram-negative anaerobic bacillus which they named *Bacterium pneumosintes* This organism, obtained from the naso-pharynx of early cases of influenza, is capable of passing through certain Berkefeld filters, and appeared to cause a febrile disease in rabbits The new organism was very difficult to cultivate, and in consequence vaccines were difficult to prepare, but vaccination on a more or less limited scale with this organism gave rather indifferent prophylactic results During the last few years a scanty amount of confirmatory evidence of Olitsky and Gates's work has appeared, but it is by no means yet proved that *B pneumosintes* is the true cause of the disease

Towards the end of 1924 the writers discovered a new medium which grew *B pneumosintes* very easily and profusely, and succeeded in cultivating it from several cases of influenza A large amount of the appropriate vaccine was prepared, and preliminary experiments showed that it was very toxic, but this vaccine has not yet been exhaustively tested as to its value in preventing the disease The position to-day may therefore be summed up by saying that we are still by no means certain as to what is the true causal organism of influenza

About six weeks ago one of us contracted rather a severe attack of typical influenza, with fever, headache, vague pains all over the body, intense prostration, slight catarrhal symptoms in the left nostril, but no definite bronchitis or sore throat. As we possessed a very good culture medium for *B pneumosintes* we determined to make an attempt to isolate this organism A swab from the left nostril was inoculated into the medium, and 5 c cm. of blood drawn off during the first day of the fever was distributed into two further tubes of the same medium All the cultures were incubated anaerobically. *B pneumosintes* did not appear in any of the tubes, but to our surprise a pure culture of an unusual streptococcus was obtained from the nasal swab and also from the blood The streptococcal cultures were plated, and the streptococcus from the nose and from the blood were found to be identical Here then we have a certain amount of reason for suspecting that this attack of apparently true influenza was due to a streptococcus which had its primary focus in the nose and which invaded the blood stream. The temperature in this particular case remained at a level of 101° to 102°C for four days The attack was followed by the usual symptoms of depression and weakness

We hope to publish full details of this particular streptococcus with microphotographs in a later paper In broth culture it is a small streptococcus occurring in fairly long chains, whilst on solid media it is extremely pleomorphic, showing large ovoid forms with pointed ends It produces strong bleaching on boiled blood agar In view of the fact that influenza is now very prevalent, we believe that the isolation of this streptococcus will be of interest to other bacteriologists

We are, Sir, yours faithfully,

AN ENORMOUS EXTRAPERITONEAL CYST

To the Editor of THE LANCET

SIR,—A Mahommedan woman aged 36 came to me with what appeared to be a huge ovarian tumour It was noticed about seven years ago, after the birth of her fourth child, and was more on the right side than the left After this she had four more children, and labours were difficult The tumour was tapped three times before she came to me I gave her morphia, gr ¼ and hyoscine gr 1/100, and an hour afterwards incised the lower part of the abdominal wall and tapped the tumour, draining it scattered disease throughout" Had tuberculin previous to his entry at St. George's House physician's chart says: "The breaking down was probably due to increasing dose of tuberculin without regard to reactions" 23/2/14 "Injection of Dr Spahlinger's *ferment*" May 7th. "The signs seem very definitely drier than on admission" June 4th (on discharge) "Signs still show improvement and the general condition of patient is better The sputum averages ½ oz daily He is putting on weight"

Considering that the patient—

(*a*) was an advanced case with extensive disease and cavitation,

(*b*) that he had antigen treatment (therefore active immunisation),

(c) that on his discharge on June 4th after three months and one week's treatment, the amount of sputum had dropped from 2½–3 oz to ½ oz. and his signs were much drier,

I consider the patient as having made a very satisfactory improvement Dr Nelson admits that he entered business, got on very well, married in 1917 He apparently broke down shortly after. This is quite possible, considering that he had an insufficient course of antigens to protect him.

CASE 5 —T T

"Case 5, T T," as given by Dr Nelson, never received my treatment at St George's or after leaving that hospital

There was a case "No 5—E T. A" which Dr Nelson completely omits to quote He was admitted at St George's on March 23rd, an early case of pulmonary tuberculosis After discharge from St George's he received a further course of treatment In answer to a letter of mine he wrote on 11/1/1921 —

> "I was so sorry I did not see you personally before you left London to thank you personally on behalf of myself and my family for your treatment which I was fortunate enough to receive through your kindness in the year 1914 I have been in excellent health since then as regards my chest trouble (thanks be to you again) Now I am doing very hard work for 12 hours a day as luggage porter I was pleased to see so many of your other old patients looking so well the other day, and from what *they told me*, they must be working about as hard as I am Again with very best thanks, etc "

He is still alive and well This is the type of case which ought to receive at once antigen treatment without a previous course of serum

CASE 6 —B M

Dr Nelson says 'Amount of sputum less at first, later increased' The registrar's notes from which these remarks are copied, say: "There was a noticeable diminution of sputum during the first six weeks, but there was afterwards an increase to *former amount*" House physician's report says April 7th: Has lost 2 lb Sputum has decreased Cough much less troublesome" and "chest distinctly drier" Chart says April 23rd "Has lately had ordinary colds increase of sputum stiffiness in head, nasal catarrh" (With colds it is not surprising if patient's sputum increases to former amount No more is said on this case)

The registrar in his abstract says: "Course of 17 injections of Spahlinger's *serum* given without any improvement" Had he properly consulted the charts he would have read March 16th Treatment commenced by Dr Spahlinger's injections of *mixed ferments*" May I point out once more that none of my *serum* was ever used at St George's The records are obviously deplorably kept The same error regarding *serum* appears in the registrar's abstract of readmission

Dr Nelson admits that on second discharge the patient's sputum was less in amount The registrar's notes say "There was on an average only *a quarter* as much daily sputum as before' Dr Nelson states Temperature at end of course tending to be more constantly febrile" I enclose photograph of this patient's last temperature chart at St George's which shows that except on two days following her injections, while reaction existed her temperature remained absolutely normal, and even subnormal, the whole time (*For five days it was normal, it rose to* 102·4° F. immediately after injection, then for five other days it was normal; then again to 104° after further injection; for 12 succeeding days it was below 98·4°. which *ends the chart*)

The patient was discharged on July 2nd, 1914. She wrote on July 28th 1914 —

> "I should very much like to continue with the treatment . . . *I have much pleasure in being able to tell you I feel quite fit In fact, I cannot remember having felt so well for some time My temperature is below normal and my appetite is excellent In fact, I am decidedly progressing famously. I might add I gained 3 lb this week in weight Trusting you will favour me with a reply as to when I can have the treatment, as I am very anxious to continue same, for I feel quite confident of a decided cure* . "

The patient was examined by several doctors and by a leading London specialist on August 10th, when she had practically no active signs in chest and hardly any sputum. She had gained weight steadily since her discharge from hospital and the dyspnœa was much improved On Oct. 23rd, 1914, she wrote:—

> "I am writing to ask if I could come to Switzerland and finish my treatment . after having derived so much benefit from your treatment I do not want to go back . . "

I enclose photographs of this patient's letter. This is a typical case of vaccine treatment; in many cases there is a negative phase (during which the patient remains stationary), followed, after a time, by marked improvement which eventually leads to recovery, provided the treatment is sufficiently prolonged I have little doubt that if this patient had continued her treatment and received a course of antigens and ferments for one year instead of only two months and a half she would not have had a relapse and would have effected a complete recovery

CASE 7.—J A

Dr Nelson *forgets to mention that the house* physician's chart says "Night sweats, severe cough with much expectoration' Registrar's notes state "Rather severe cough with much yellow sputum, profuse and frequent night sweats' The original charts say: 'There is evidence of tuberculous disease over the whole of right chest,' and not only in upper two-thirds of that lung as Dr Nelson states He also forgets to quote 'Physical signs point to the existence of consolidation and cavities of both apices and of general infiltration of the rest of the right lung. The X ray examination showed the left side more opaque than the right'

The house physician's report of April 18th states: 'To-day he has had an injection by Dr Spahlinger' No definite reference to what was injected is traceable on the charts Yet the registrar says in his abstract: "During April to July a course of 17 injections of Spahlinger's *serum* were employed' Once more let me make it clear that *none* of my serum has ever been used at St George's If the registrar had carefully studied the charts he would have read "26/6/14 . . reactions vary in severity, but all of the same type (i e, similar to phenomena seen in tuberculin reactions)' This remark should have shown the registrar that antigens (the contrary of serum) were used

Dr Nelson unfortunately, repeats the registrar's error by using in his comments the words: "Smart reactions, especially with the *serum*" This shows plainly—

1 That Dr Nelson did not carefully read the hospital records, otherwise he would surely have seen the remarks of 26/6/14 comparing the reactions with tuberculin reactions

2 That Dr Nelson is not an authority on specific treatment of tuberculosis and has no knowledge of the mode of action of sera or antigens (tuberculin also is an antigen) Dr Nelson adds "sputum decreased' but he forgets to continue "from 4 to 1 drachm daily" as is mentioned by the registrar. This is important, especially with antigens in such short a period of treatment. Dr Nelson says further "weight as before" This is a slight error. The

TREATMENT OF TUBERCULOSIS BY MR SPAHLINGER'S METHODS

To the Editor of The Lancet

Sir,—Dr Nelson refers to "cases treated under the immediate supervision of Mr. Spahlinger himself between *November*, 1913, and *August*, 1914" The dates are inaccurate The first injection made with my preparations at St George's was Feb 23rd, 1914, and I had never entered St George's before February, 1914 I have before me a photograph of a letter (the original of which is in my safe) from Dr Latham to me, dated Feb 14th, 1914, in which he says —

> "I was glad to hear that you were ready to treat some cases in St George's Hospital If you could meet me there at 2 o'clock on Wednesday, we could then see what cases I may have and arrange matters"

I had never even entered this hospital in 1913 I challenge Dr Nelson to prove his claim

"*There was about an equal number of cases treated at the same time under similar conditions, in nursing homes,*" says Dr Nelson This is absolutely untrue, and I defy Dr Nelson to give the names of "a number of cases" which I had treated with Dr Latham at nursing homes

I will proceed to deal with the individual case records quoted by Dr Nelson, seriatim

Case 1—I H

Dr Nelson's quotation regarding R lung seems wrong, as the hospital charts say "moist sounds over lower lobe of R lung which is probably also tuberculous . . and crepitations over R lower lobe"

The St George's Hospital charts contain the following —

Feb 23rd First injection of Dr Spahlinger combination of ferments and antigens given (The chart says explicitly "*ferments and antigens*" and not serum, as is stated in error by the registrar It will be noted that treatment started on Feb 23rd, 1914)

27/4/14 Sputum report says Sputum very much less purulent than that usually received

6/5/14 Report says Physical signs seem very definitely drier than previously

26/5/14 Specimen of sputum of 25/5/14 shows only 3 T B, and these only by the antiformin method

The registrar's notes are wrong when he says "A course of 26 injections of Spahlinger's serum was given" None of my serum was ever used at St George's

This patient was discharged on June 9th The patient, therefore, who was obviously of an advanced type (as is admitted by Dr Nelson) had three months' antigen treatment, the last report, on which the registrar's notes are based, is dated 26/5/14, the previous injection having been given on 22/5/14 In my opinion, to obtain with antigen and ferment treatment in three months' time such improvement as is indicated by the drying up of physical signs, diminution of purulence of sputum, and almost the disappearance of T B in sputum, is highly satisfactory I am of opinion that any unprejudiced expert would be satisfied with this marked improvement Dr Nelson says this patient has not been traced, she may be dead or still alive To me she was reported as alive and well in 1923 when I tried to trace her But, as I have not seen her personally nor had a letter from her, I prefer to make no statement on this point at present All I claim is that this patient made a very satisfactory improvement in three months' treatment

Case 2—A H

As Dr Nelson admits that this patient was alive in 1926, the only comment I wish to make is this Dr Nelson's statement says that under previous gold treatment she lost 5 lb in weight, under my treatment she gained 5 lb To my recollection her lupus was much improved, but I have unfortunately, no photograph to prove it

Case 3—M H

Dr Nelson's report quotes "early tuberculosis of larynx" St. George's Hospital records say 'Larynx, 14/1/14, considerable tuberculous ulceration affecting R arytenoid, chiefly, and interarytenoid space" Another hospital report says "Tuberculous ulceration extending to left arytenoid; infiltration of both aryteno-epyglottidean folds, three small tubercles on the edge of the epiglottis Chest Signs point to massive disease which appears to be on the point of breaking down X ray reports Extensive tubercular disease in both lungs There appears to be a large cavity at the L apex and several smaller ones scattered *throughout the left lung*"

Dr Nelson's report says that during her course of gold treatment she lost 4 lb, but that her signs remained stationary. He forgets to quote from the hospital records the passage "Except for more marked signs of excavation at L apex" 13/3/14, another chart says "Very marked signs now of excavation left upper lobe in front" 7/4/14 Next chart says "Commenced with injections of Dr Spahlinger's *ferments* since yesterday"

My comments on this case are as follows —

1 She received ferments and no serum 2 She commenced my treatment on April, 1914, and therefore could not have been under my care since November, 1913 3 During the week preceding the beginning of my treatment she had a quantity of sputum varying from ½ oz to 2 oz The last six days before her discharge she had from 0–½ and then, four times, a trace 4 Regarding sputum test, report of June 13th, 1914, signed Hunt, says

"T B present They are rather scanty compared to what was seen in sputum specimens 3 or 4 months ago" That is what Dr Nelson calls "T B + rather fewer" 5 From which chart does Dr Nelson get his statement. "Physical signs unaltered"? If he will present the original chart I shall be greatly interested 6 On one of the charts the last clinical examination is entered against the date April 18th Then there is written on the same chart (about the middle) merely the date "May 2nd" All the rest of the page is blank There is no mention of the examination which apparently ought to have been made on May 2nd 7 One other chart, signed "J W L," ends at the date May 11th The hospital records regarding this patient are *incomplete* and badly kept She was discharged in July

My conclusions on this patient are This was an advanced case, both lungs as well as the larynx were involved The patient was treated with antigens *therefore, she was being given active immunisation* treatment during three months and eight days There was a loss of weight of 4 lb With regard to the physical signs on discharge, perhaps Dr Nelson will oblige me with the original hospital chart quoting examination on discharge Sputum decreased from ½–2 to 0–½ T B decreased from numerous to scanty

In his summary Dr Nelson calls this case "slightly worse" I call it, if anything, better, and one cannot expect more in an advanced case with antigen treatment (active immunisation) in such a short period I never troubled to trace this case as it had not received the full course of antigen treatment, which, in such a case, would have required several months longer I expected the patient would be dead—not as a result of any inefficacy of my antigens, but owing to insufficient length of treatment

It must be remembered that with serum treatment the patient receives the defences ready made by the horse, hence the rapid improvement With the antigen treatment (active immunisation) the patient must manufacture himself his own defences, and there is, therefore, generally a negative phase It takes a considerable time before these *defences* are properly trained to fight, and the time is specially long in advanced cases where very small doses of antigens must be used to avoid such disasters as those referred to at the beginning of the next case and attributed to tuberculin by the house physician

Case 4—M C

The hospital charts contain the following "Massive disease of upper half of R lung with cavitation, L lung upper lobe affected (possibly massive disease), and expenses of my researches surely I was entitled to have a duplicate of case records ? Copying was taking too much time I therefore asked for permission to photograph each sheet I received this permission and was even helped in my work by some members of the medical staff

Summary of Conclusions

1 Dr Nelson's article bristles with inaccuracies about case records, dates, and the remedies employed In some of his quotations he omits important words or interpolates remarks of his own

2 To the ordinary reader who rarely has time to read the whole details of the cases, and therefore glances chiefly at "conclusions," Dr Nelson's article would convey the impression that ten cases were treated by my method for ten months, when in reality the longest period of treatment was five months. One patient had only six days' treatment and another three weeks' treatment

3 He is wrong when he says that only one case is alive—three are alive (out of eight, not out of ten, two cases, as I have shown, are invalid for purposes of comparison)

4 He is wrong when he says that no cases were *cured—three were cured*

5 He is wrong when he says that only four cases made a *slight* improvement Immediately on cessation of treatment five cases showed considerable improvement, which eventually led in *three* of them to complete recovery It is possible that a *fourth* case (No 1) is also well and alive, but she was not traced lately

6 He is wrong when he says that Cases 3 and 6 were worse Case 3 improved and Case 6 improved very markedly, especially during the two months following her discharge from St George's In fact, none of the cases became worse, in spite of the fact that they were severe cases and that antigen treatment was used This in itself is a tribute to the value of my antigens

7. He is wrong when he states that Dr Latham found my remedy ineffective Dr. Latham himself stated that the results were sufficiently encouraging to warrant a thorough trial of the method Dr Nelson recognises that Dr. Latham was a "very learned and wise physician whose opinion in such a matter would carry almost universal conviction "

If serum treatment had been used the results would have been more rapid Vaccine (or antigen) treatment only shows its positive results after a much longer period of time, also, the full benefits derived from the treatment are only evident when a few days have elapsed since the last injection to bring about a specific focal reaction, followed by local and general symptoms These, which are of a temporary nature, only disappear in the course of, say, 10 to 20 days

8 May I further quote Dr Nelson's own words · "They are the sort of cases in which an arrest of the disease with a return to reasonable health and life on the part of several of them would have indicated the presence of a curative agent in Mr Spahlinger's preparation . " Those patients who *received* a course of treatment sufficient for their condition are still alive; those who had an insufficient course are dead What *better proof of the* efficacy of my work does Dr Nelson wish ?

I am, Sir, yours faithfully,

H SPAHLINGER

Institut Bactériothérapique, Carouge, Genève,
Jan 11th, 1927

To the Editor of THE LANCET

SIR,—As I was associated with the late *Dr* Arthur Latham in the treatment of cases of tuberculosis with Mr Henri Spahlinger's preparations, and as it was on my suggestion *that Dr Thomas* Nelson sought out the after-histories of the cases treated, it may not be out of place for me to write a few lines commenting on some of *the points* raised by Mr Spahlinger's long letter

The cases treated at St George's Hospital were chosen by Dr Latham and myself together, *all the* injections were performed by me full private notes (entirely separate from the hospital notes, which I was in the habit of supplementing) on the history and progress of cases were made by me for Dr Latham and nothing, to my knowledge, was revealed to him by Mr Spahlinger of which I was not cognisant

At our first interview with the latter at St George's, Dr Latham rightly insisted that we must know the contents of his preparation before we used it "Your methods of manufacture," he said "may be secret, but we must know *broadly* its constitution " Mr Spahlinger replied that the preparation consisted of ferments extracted from various organs (the spleen especially) of tuberculous animals passed through a special filter of his own invention to remove "the harmful tryptic element " On several occasions during the treatment of cases at St George's and elsewhere he handed me something evidently different to inject, which I feel sure he referred to as his "serum." Mr Spahlinger is a foreigner, and, as the St George's Hospital bacteriologists complained, his terminology was naturally, to our way of thinking, loose

Dr Latham and I asked him at the outset how long a course would be required in view of the question of beds, on this point he was never very definite as far as I can remember, but he assured us that all the phthisical patients would lose the bacilli from their sputum in at least six weeks, and there would be such *remarkable* improvement that we, who were, unlike him, physicians, could then judge for ourselves. These promises of dramatic improvement were, unfortunately, not fulfilled

I well remember another series of cases treated about the same time outside the hospital, which I watched for Dr. Latham Fortunately, Dr Edward Hunt, bacteriologist to St George's, accompanied me on at least one occasion to the house where these cases were treated, and is, of course, willing to attest to the fact I think that Mr Spahlinger should remember this series of cases, as I always understood that he paid for the expenses of nursing, &c —but maybe it was his father who paid and he has forgotten Anyhow here again he assured me that certain cases of lupus selected for treatment among others would be cured in six weeks They did not appear materially benefited in my opinion at the end of a longer period I was genuinely sorry to have to tell him so, as he always appeared to me in those days a sincere enthusiast—and there we parted ! I reported to Dr Latham and, at his suggestion, went away for a holiday, the war came almost directly ; I crossed with the Expeditionary Force; on my demobilisation I found Dr Latham an ill man, we never resumed our intimate association in work ; I never discussed the Spahlinger cases with him again, and, as all know, after a long illness he died

Mr. Henri Spahlinger is not a qualified physician, *it is often difficult* for physicians of even high standing, who have not lived in chest hospitals, to appreciate fully the frequent and often long *remissions* which stay the downward course of the average chronic consumptive under no special treatment of any kind, and also the *wonderful* benefit derived from rest, especially absolute rest, in bed Maybe none of us yet appreciate fully the effects of injections of *foreign* protein *Dr* Latham had not only a wide experience of pulmonary tuberculosis, but he had also that enviable gift of restrained optimism *so necessary* to research ; he always encouraged, while he watched and waited

One often thinks *that the curative* effects of any new treatment for pulmonary tuberculosis must now be dramatic to be convincing It is now just on 13 *years since I* first met Mr Spahlinger, during which time several hundreds of thousands of people have died in this country alone of tuberculosis, *and the* essential details of his method remain undisclosed

I am, Sir, yours faithfully,

Harley street, W, *Jan 24th, 1927.* J W. LINNELL.

To the Editor of THE LANCET

SIR —I must thank you for showing me Mr. Spahlinger's letter and giving me the opportunity of answering it at once I will immediately give Mr.

patient put on 2¾ lb between the beginning of my treatment and discharge

Dr Nelson states "signs the same" Is he aware of the fact that after an antigen reaction all signs in the chest are temporarily more active on account of the focal reaction which follows? One can only give a considered opinion on signs in the chest when at least ten days have elapsed since the immediately preceding specific focal antigen reaction The last chest examination was made the fifth day after the last reaction (From 98 4° F temperature went to 102° F, to drop again to 98° F the following night) Had this examination been made five days later I am convinced that instead of "signs the same" he would have found "signs much drier" This remark applies to all the cases quoted in Dr Nelson's article

Again, Dr Nelson forgets to quote from the registrar's note, "the general condition was improved" This patient wrote to me from Edinburgh in his own handwriting on 25/11/20, saying —

> "*In 1916 I* started working again at the back of the counter and in 1917 after many rejections I was passed A1 for the army Unfortunately, my people didn't want me to go and appealed to the military authorities, consequently I was discharged Since then I have been in charge of the paper department and stationery factory, and keeping well I can do my round of golf after business hours and have a night's dancing without feeling any the worse"

This letter speaks for itself No comments are necessary The patient may have died in 1921, as Dr Nelson says But what was the cause of death? A relapse after these six years of good health might be attributable to an insufficient course of vaccine If it were, it would strengthen my argument that antigen treatment should be strong in early cases, or, in those more serious cases where it could not be administered in large doses it should be given over a long period

CASE 8.—G E

The house physician's report states "Pott's disease, the over-lying skin is thickened and inflamed Some local tenderness," whereas the registrar says "Angular deformity of lower dorsal spine with thin and inflamed skin over it" Was it thickened or thinned? Dr Nelson states "lungs have a poor air entry at left base, otherwise not *abnormal*" But the hospital charts classify the patient as "caries of spine (tuberculous) and chronic pulmonary tuberculosis" House physician's report states "Chest No gross evidence of T B" Another chart says "Creps at left base behind X ray report, however, 'general mottling of both lungs suggesting tubercular disease'"

The registrar's report says "Lungs suggest tubercular infiltration at left base" The chart also mentions "losing weight" In this case also the registrar mentions that injections of Spahlinger's *serum* were given Here again he is wrong There is no reference to serum on any of the charts Dr Nelson is repeating the same error regarding sera The registrar's notes mentioned that the patient was *slightly improved* Dr Nelson makes no reference to that improvement, which a specialist might call more than slight, considering that the admission chart contains the words "difficulty of turning over in bed," and that the chart of discharge says "no difficulty in walking afterwards"

On July 28th, after her discharge from St George's, this patient wrote asking for further treatment She said —

> "I feel sure that if I had a few more injections I should be permanently cured"

I paid her expenses for a further stay in London and she received some more injections At the end of August her condition was as follows No pain, local tenderness disappeared Patient feeling stronger, able to walk without any trouble

On August 5th, 1921, she wrote again "My healing is certainly wonderful" No further comments are necessary

CASE 9.—F B

The registrar's notes say "Under observation for six weeks For first three weeks he was up daily, the temperature was highly irregular and swinging the sputum became more copious and contained abundant T B The signs became moister and suggested cavitation at right apex During the remaining three weeks three injections of Spahlinger's serum were given Each was followed by constitutional and febrile reactions and the temperature was rather less swinging and lower He was removed by parents on June 13th before further injections had been tried, his condition being practically the same as on admission"

It is useless to comment on this case, which had only one week's antigen treatment (three injections), except 1 To notice that here also the registrar calls my antigens "serum" 2 Why does Dr Nelson say "only three injections of Spahlinger's cure given"? 3 The way Dr Nelson puts the case seems to imply that the parents had removed the patient because he felt worse The three injections of antigen he received certainly did not make him worse The registrar says explicitly that "his temperature was rather less swinging and lower" Other symptoms *status quo*

CASE 10.—M O

The registrar's note says "She was under observation for two months The temperature throughout was extremely irregular and signs tended to become more extensive During June she had six injections of Spahlinger's serum, but without obvious benefit, there being progressive loss of weight and no change in amount of sputum and of T B therein contained" Same remarks regarding antigen, called "serum"

The patient had only three weeks' treatment Very small injections of antigen were given on account of the severity of this case Surely no specialist could expect such a case, when given active immunisation treatment, to show positive results in a few days, and it is ridiculous that Cases 9 and 10 have even been mentioned by Dr Nelson It would be better to say "Two further cases received a few injections, but the period of treatment was too limited to permit any conclusions being made one way or the other"

Since publishing his article Dr Nelson has made further comments on my work "To my knowledge Dr Latham tested innumerable 'remedies' for tuberculosis, caring hardly at all from what source they came He found them all ineffective, including that of Mr Spahlinger," he says Unfortunately for Dr Nelson this statement does not correspond with the facts, nor with Dr Latham's opinion The latter is expressed in a document written in his own handwriting, when he asked me in 1914 to publish a statement on the cases we had treated at St George's Here is the document —

> "Short scientific account of the method
>
> "Then a statement to the effect that a number of cases have been treated at St George's, etc, etc, under the care of etc, etc, and that the results, although sufficient time has not yet elapsed to speak definitely, are sufficiently encouraging to warrant a thorough trial of the method"

Dr Latham was delighted that such severe cases were responding favourably *to antigen treatment*, and he had asked me *to call on him in order* that I should publish an article on the subject He was quite aware that the cases had not *had time to be* cured, hence his words "sufficient time has not elapsed to speak definitely", yet they had made enough improvement for him to say "the results are sufficiently encouraging to warrant a thorough trial of the method"

Dr Nelson claims that I had *no right* to photograph the hospital records How absurd! Here are the facts Three months after the war *had broken out* I decided to return to Geneva *as my supply* of antigens was running short Supplies of serum had long before been exhausted I asked for permission to copy the charts so as to be able to consult the records After all that I *had* incurred in the work invariably migrate out separately and not in sheets (see Fig 1 and Fig 2 in my paper in THE LANCET of Feb 21st, 1925) In solid media such as plasma on the contrary, the appearance of sheets of cells is common

2 That these migrating cells are indeed cancer cells is indicated by the fact that when inoculated into mice they cause cancer.

3 Every cell in Fig 3 A is indubitably an M_{63} cell and the cells in Fig 5 A are human cancer cells, the superficial resemblance to fibroblasts ceases to be misleading after some experience The serological reactions. nuclear characteristics type of granules early migration &c all demonstrate the malignant nature of these cells.

I should be happy to show Dr Mottram in my laboratory the appearances of human and mouse cancer cells when cultured in a liquid medium

I am, Sir yours faithfully.

TRAUMA AND TUMOUR

To the Editor of THE LANCET.

SIR—May I trespass upon your space to ask if anyone has met with the development of a tumour in a wound inflicted upon a combatant during the late war? If mere traumatism can induce carcinoma or sarcoma it would be natural to expect examples from so great a wealth of material

I am. Sir. yours faithfully.
G LENTHAL CHEATLE

Harley-street, W 1, Jan. 24th 1927

MEDICAL TEACHING ON BIRTH CONTROL

To the Editor of THE LANCET.

SIR—In his address to the Manchester Medico-Chirurgical Society. reported in your last issue. Dr. Giles makes a statement at variance with the experience of normal women who use contraceptives. Speaking of the mechanical prevention of the entry of spermatozoa into the uterus he says of the devices for this purpose: "their chief virtue is that they are a source of revenue to those who sell them" As one who has never sold them and never will. but who owes her life to their use. may I. in the name of normal womanhood point out that this misrepresentation is made by one obviously unacquainted with the profounder essentials of contraceptive knowledge and practice.

I agree with Dr Giles that there are a number of "so-called birth-control clinics" which advise without selection of suitable cases or a discrimination of the various means of contraception The clinic which I have founded is run on scientific lines. and is supported by many of the leading medical men and women of the day The commercial imitators are to be deplored. but they would not have come into existence had not the Ministry of Health interfered with medicals in its employment and hindered them from seeing that suitable contraceptive information was freely available thus making it commercially profitable for unscrupulous firms to foist on the public expensive articles bought by trustful women who are in such misery that birth control contrivances are the prime necessity of their lives. It is within my own knowledge that rubber and metal articles costing at wholesale prices less than a couple of shillings are retailed at prices up to three guineas each since the higher the price the more do the poor women trust in their efficacy.

The advice on methods given by Dr. Giles in his article contributes nothing to the scientific knowledge of the subject All and more was contained in my small popular book published eight years ago and more fully set out in my book Contraception—Its Theory. History and Practice," published in 1923 If Dr. Giles has learnt no more of contraception than to say "the condom plan is the best," he will not satisfy intelligent women.

Finally I must contradict Dr. Giles's statement that the least harmful plan is the restriction of intercourse to the 'safe period." Where both of the couple are normal and healthy there is no "safe period." and where there is its use involves the coercion of a physiologically unready woman at times and the refusal of her at other times when she is ready for coitus. both of which are barbarous and immoral.

I am, Sir, yours faithfully
MARIE C. STOPES
President, Society for Constructive Birth Control
and Racial Progress

Whitfield-street London, W, Jan 24th, 1927

DEATHS UNDER ANÆSTHETICS

To the Editor of THE LANCET.

SIR,—In your annotation on my paper published in your last issue. you suggest that an increase in recent years in the number of operations of a severe type may account in part for the greater number of the anæsthetic deaths set out in the tables published by the Registrar-General I may point out that these statistics purport to deal with deaths under or connected with anæsthetics" and it is not clear how deaths due to the severity of an operation can be returned in this category. However. I do not think it necessary to debate this point. because the Registrar-General publishes a list every year of the number of anæsthetic deaths returned as occurring under specified operations which shows that the great bulk of the deaths occur under operations of a less severe type and further that these, collectively, bear practically the same proportion to the full total of the deaths in 1924 as they did in 1911. If your suggestion had any serious significance. I think it would have been reflected in these figures I must apologise for thus trespassing further on your space, but I think that in considering the Registrar-General s returns. care should be taken to free them from any suggestion which might tend to confuse the issue—I am, Sir. yours faithfully.

A. G. LEVY.

Manchester-square W 1 Jan 24th, 1927

STREET ACCIDENTS IN LIVERPOOL.—As reported to the police of Liverpool during 1926 there were 64 persons killed and 3937 injured The total number of accidents was 3717. and 2538 mechanically-propelled vehicles were involved There was an increase of 13 fatal accidents as compared with the previous year

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.—At the opening meeting of the spring session Dr. Maitland Ramsay gave an address on Toxic Iritis. He deprecated the use of the term rheumatic iritis because. though sometimes associated with chronic arthritic states. iritis practically never occurred in rheumatic fever. He had chosen the subject, he said, because it so aptly illustrated the general principle that the cause of disease was not necessarily to be found in the organ manifesting the symptoms. Toxic iritis being a local manifestation of a general state local treatment was essential to its relief, but cure was not obtained until general treatment removed the underlying cause and so prevented recurrence. For success general treatment must depend upon recognition of the toxic process. In many cases the *focus of* infection was found in the teeth. tonsils. nasal sinuses or intestinal tract but in others it followed after an attack of some general infection such as influenza. In some cases the source of the infection remained a matter of conjecture and in these circumstances the iritis was spoken of as idiopathic but it was very difficult to understand how an iritis could occur in a healthy patient. In those cases, for example in which posterior synechia interfered with the intra-ocular circulation and tension the local symptoms were intense. The relief afforded by iridectomy was so complete that apparent cure resulted but if general treatment was discontinued recurrence of the inflammation in the affected or even in the healthy eye was to be expected Operation was a confession of failure and disaster would inevitably follow if its dramatic results should lead to neglect of general treatment.

Spahlinger credit for his only correct statement When I used the words November, 1913, to August, 1914, this was the complete period the cases treated by Mr. Spahlinger were under observation by Dr Latham As is made quite clear in the detailed notes the first case was not treated by Mr Spahlinger until February, 1914

I commenced to answer his specific charges one by one Where I could make out the exact nature of his grievance I soon found that the same answer applied to them all By taking individual notes apart from their context, Mr. Spahlinger attempts to show that I have made deliberate errors in description and in fact I see, however, on going over them again that my much condensed accounts of very voluminous notes are all perfectly fair summaries of the history, extent and severity of the disease and changes after treatment I was aware that I might be accused of bias, so that where I have summarised the mildly conflicting facts and reports that will occur in any notes, I always gave to Mr Spahlinger the benefit of any doubt

Two examples from Mr, Spahlinger's own quotations will suffice to show what I mean, to keep them to concrete facts we will take the sputum reports of the first two lung cases In case No 1 he makes a great deal of the "three T B found by the antiformin method," dated 26/5/14 Having the notes in front of him, and speaking in the interests of truth, he has not told you, Sir, that the very next report, dated June 3rd—six days before the patient's discharge—says "T B present, 30 to 40 per field" I did *not* take this report alone, because on studying the many and careful reports (by Dr E L Hunt) as a whole, there certainly *was* a diminution of T B in the sputum. I made that appear, perhaps, even more so than it really was by quoting the "antiformin" report Again, in case 3 Mr Spahlinger seems to object to my translation of Dr Hunt's report—which he quotes—as "T B plus, rather fewer" He has not the advantage of seeing the private additional reports kept by the bacteriologist in his laboratory for his own information This very report also says "Many fields show none, some fields show 10 to 20 bacilli singly or in little groups" Under the circumstances I think my summary is very fair indeed

I might continue this kind of example in every case I am not in a position to reply to Mr Spahlinger's reference to personal relations with Dr Latham, so I have taken the liberty of showing the letter to Dr Linnell, and I hope you will be able to print his reply He will also finally dispose of Mr Spahlinger's reiterated statement that there were no cases treated in a nursing home outside St George's For some reason Mr Spahlinger wishes to forget these cases, among them was the poor fellow, T T, who died so rapidly after Mr Spahlinger's treatment The case of E T A. I was able (owing to the kindness of Dr Leonard Williams) to show had no tuberculosis by publishing the full notes in a letter to THE LANCET of Jan 15th But Mr Spahlinger, with these notes in front of him, still includes this case as a cure of tuberculosis There can be no doubt that Mr Spahlinger has the notes, he says so But there is no record in the minutes of the House Committee or of the Medical School Committee that he was given leave to copy them.

Mr Spahlinger is highly indignant with me for using the word "serum" in inverted commas, which I did twice where it occurs in the notes Elsewhere I have used the word "preparation" or some equivalent "Serum" was not used in any scientific or pseudo-scientific sense, for neither I—nor presumably the clerk who wrote the notes—would wish to pose as an expert in the nomenclature of secret preparations

I would not weary you, Sir, by dealing with the inconsistencies in every line of Mr Spahlinger's letter He complains in one place that I have not given due emphasis to the isolated report of a lung being drier, and a few laps later says that another lung should not have been noted as wetter than it might have been if it had been less wet if examined when it ought to have been drier—at least that is the best I can make out of it Briefly, I gather that he is really disgruntled because I have not inserted and underlined every favourable comment and suppressed every sign of deterioration in the patients

Perhaps I had better explain Nos 3 and 4 of Mr Spahlinger's "Summary of Conclusions" One case is certainly alive—lupus Of the other two Mr Spahlinger says are alive, one is the spurious case of E T A, which of the *untraced* cases he assumes to be living is not clear Presumably it is No 1 who, he says, was alive in 1923, but omits the simple information by which this might be verified My inclusion of the case No 9 was for completeness, one can argue little from it No 10, however, was getting so rapidly worse under Mr Spahlinger's treatment that even he could see it and desisted

In my original article I endeavoured not to express even an opinion that might seem prejudiced, and I made the lenient comment that "such slight indications as there are of improvement are not more than one would expect from tuberculous patients after they had been in bed for periods of time such as these were" I suppressed my own conviction that they were worse than if they had had no treatment but simple rest in bed, and much worse than if they had been kept on "absolute rest" for these periods

I am, Sir, yours faithfully,

Brook-street, W, Jan 24th THOMAS NELSON

⁎ We have gladly allowed Mr Spahlinger all the space he desired, in this issue of THE LANCET, in which to reply to Dr Nelson, whose rejoinder, along with a letter from Dr Linnell, is printed in the same issue for the convenience of our readers Mr Spahlinger in some preliminary observations (which are omitted) reproaches us for not having published in 1923 an account by Dr Ogle of the cases treated by Dr Latham at St George's Hospital This account was mentioned by Mr Spahlinger personally to a member of our staff, but was, in fact, *never submitted for publication* His second reproach is that, since August, 1923, THE LANCET has systematically refused to publish anything referring to his treatment by those who have had actual experience of the cases, while it has published several unpleasant attacks by people who obviously did not know the facts Yet he grants that detailed clinical records appeared in THE LANCET of that year, just prior to the date mentioned, under the names of Colbeck, Gloyne, Hudson, Lardy, Savoie, Stephani, Trechsel, and others—Dr Nelson in his paper did us injustice, as he is good enough to admit, by overlooking these records A résumé submitted by Dr Leonard Williams was returned to him on August 3rd 1923, simply because we felt, as was made clear at the time, that the case for the remedy had been stated by its advocates and that nothing further could usefully be done until a supply of it was available for extensive test under controlled conditions. Dr Williams's paper subsequently appeared in the *British Medical Journal* which had not then dealt with the subject That is all three years ago, but Dr Stephani, Mr Spahlinger's principal supporter in Switzerland, wrote to us on Jan 15th last, stating that he had always found THE LANCET "anxious to show every impartiality concerning the sundry reports about Spahlinger's discovery " The fact is, as any unprejudiced reader may see for himself, that THE LANCET has during the last 12 years faithfully presented such clinical evidence as is available of the value of Mr Spahlinger's preparations and has never ceased to reiterate, at the risk of being tedious, its appeal to Mr Spahlinger to put these preparations to a convincing test of their utility —ED L

IMMUNITY TO IMPLANTED TUMOURS

To the Editor of THE LANCET

SIR,—The points raised by Dr Mottram were considered and settled years ago

1 From the study of over 2000 cultures it is seen that M_{63} cells cultured in my liquid serum medium,

was admitted an honorary Fellow of the Royal College of Surgeons of England, and only a few days before he died he was gratified to see a reference to his work for renal surgery in the bicentenary issue of *Guy's Hospital Gazette* Mr Larkin's clear mind and confident judgment showed to advantage in the celebrated Wainwright trial of 1875, when his accurate evidence was largely responsible for the prisoner's final conviction, winning handsome recognition from the Lord Chief Justice The care and thought which he brought to the solution of a forensic problem was also applied to his surgical work, and especially to the treatment of fractures As a boy he was much in contact with agriculture and engineering and in his hobbies as in his work he showed a mechanical turn of mind In later years he took a keen interest in gardening and farm work at his home at Grove Park During most of his life, however, Mr. Larkin's especial interest was in music. This enthusiasm dated from an early association with Canterbury Cathedral, not far from his birthplace at Hoath In early days of practice he was choirmaster at Holy Trinity Church, Southwark, and later he held the same office at St Augustine's at Lee For many years also he was intimately associated with Westminster Abbey, where his old friend, Sir Frederick Bridge, was organist As deputy also he sang in the choir at the jubilee celebrations of Queen Victoria and at the coronation of King Edward and King George, and he was, himself, the composer of a number of chants and of other church music

Mr Larkin leaves a widow One of his sons is Dr Reginald Larkin, of Southwark

JOHN WEBSTER, F I C

SENIOR OFFICIAL ANALYST TO THE HOME OFFICE

Mr John Webster, senior official analyst to the Home Office and pathological chemist to St Mary's Hospital, died suddenly at his home in Hanwell on Jan 20th at the age of 49 He was born in the Midlands of Quaker stock and was educated at Mason's College—now incorporated in the University of Birmingham Here he studied chemistry for three years in preparation for the examination of Associateship of the Institute of Chemistry of Great Britain and Ireland, which examination he passed in 1901, becoming F I C in 1904 Later he acted for some years as assistant examiner to the Institute in the examination on the Chemistry and Microscopy of Food and Drugs, which is recognised by the Ministry in connexion with the appointment of public analysts Webster's first post was that of assistant analyst to Sir Thomas Stevenson, of Guy's Hospital, who was then senior scientific analyst to the Home Office On the death of his chief in 1908 Mr Webster moved his laboratory to St Mary's Hospital, where he worked under Sir William (then Dr) Willcox, who succeeded Stevenson in his official connexion with the Home Office In 1909 Mr Webster was appointed demonstrator of pathological chemistry in St Mary's Hospital Medical School, a post which he held to the time of his death in conjunction with that of pathological chemist to the hospital and assistant director of the Department of Chemical Pathology of St Mary's Hospital Institute of Pathology and Research In 1919, on the retirement of Sir William Willcox from this office, Mr Webster was appointed senior official analyst to the Home Office, a post for which years of study of toxicological problems from the medico-legal aspect had made him eminently fitted to hold

An acknowledged expert in technique, Webster's original publications were not numerous He was always ready to place his chemical knowledge and experience at the disposal of his colleagues at St Mary's Whatever the pressure of his forensic duties his readiness to further the clinical applications of chemical work never failed, it is exemplified in a paper on Cœliac Infantilism, contributed by him jointly with Dr Reginald Miller and Dr H Perkins to THE LANCET in 1920

His interest in the excretion of arsenic, originally aroused by cases of poisoning, was extended to the effects of salvarsan therapy in the arsenic content of the tissues In May, 1916, he presented to the Society of Public Analysts the results of some analyses showing the relative amounts of arsenic found in the various organs after injections of salvarsan, drawing special attention to the high percentage found in the kidneys During the war Webster's activities were largely taken up by researches on the toxicity of trinitrotoluene, and he elaborated a simple test known as Webster's test for the presence of T N T in urine which was set out in an official communication from the Ministry of Munitions (see THE LANCET, 1916, ii, 1926) The test was not difficult to perform, and when efficiently carried out demonstrated the presence of T N T in varying degree in the urine of nearly all those who were working with this substance The value of the test was twofold—first in clinching a doubtful diagnosis in clinical symptoms and secondly in watching the clearance of T.N T from the system after isolation from T N T, and judging whether the precautionary measures taken had been effective

The general public got to know Webster's name through his evidence in connexion with many of the celebrated cases of poisoning, in which he was often associated with Sir Bernard Spilsbury, and formerly also with Sir William Willcox This publicity was distasteful to one who was reserved and retiring in private life, his chief recreation being music Mr Webster was popular with the students at St Mary's and was always ready to help in planning and conducting the musical part of any programme arranged by students' societies He will be missed alike by students and colleagues

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 15TH, 1927.

Notifications —The following cases of infectious disease were notified during the week Small-pox, 675 (last week 342), scarlet fever, 1493, diphtheria, 1109, enteric fever, 36, pneumonia, 2016, puerperal fever, 58, puerperal pyrexia, 131, cerebrospinal fever, 9, acute poliomyelitis, 15, acute polioencephalitis, 4, encephalitis lethargica, 41, trench fever, 1, dysentery, 8, ophthalmia neonatorum, 140. There was no case of cholera, plague, or typhus fever notified during the week

The cases of small-pox were reported from the following counties Derby, 28 (2 from Derby, the remainder from six urban and rural districts), Durham, 349 (6 from Gateshead, 2 from South Shields, the remainder from 26 urban and rural districts, the highest figures being Shildon 50, Chester-le-Street 47, Lanchester 34, Brandon and Byshottles 33, Easington 32, Hetton 20, Crook 19, Jarrow 19, Auckland 16, Willington 13, Sedgefield 10), Hereford 1 (Dore R D), Lancaster, 11 (10 from Southport, 1 from Lytham St Anne's) Lincoln, 4 (Gainsborough), Northumberland, 10 (6 of these from Newcastle), Nottingham 5 (Sutton-in-Ashfield 4, Misterton R.D 1), Yorks North Riding, 1 (Middlesbrough), Yorks West Riding, 266 (157 from Sheffield, 1 from Bradford, the remainder from 12 urban and rural districts, the highest figures being Doncaster 42, Mexborough 29, Keighley 15, Swinton 9, Thorne 7)

Deaths —In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 34 (0) from measles, 6 (2) from scarlet fever, 64 (20) from whooping-cough, 38 (7) from diphtheria, 46 (7) from diarrhœa and enteritis under two years, and 326 (137) from influenza The figures in parentheses are those for London itself.

SUSSEX PROVIDENT SCHEME —The Sussex Provident Scheme for hospital and specialised medical services continues to grow Its headquarters are at Brighton, and the scheme is one by which payment of £1, £1 10s or £2 a year entitles single persons, married couples, or families to full benefits from the coöperating local hospitals During 1926 these hospitals received £7750, compared with £6377 in the previous year A similar scheme has been adopted in the Crowborough district

Obituary.

THOMAS CLAYE SHAW, M D , F R C P Lond

The death of Dr Claye Shaw spells the loss of a recognised leader in mental medicine, for although he had lately lived in complete retirement, he was for a long time one of the foremost figures in asylum administration, and had handled all the medical, legal, and social questions associated with mental disease and failure

Thomas Claye Shaw was born at Stockport in 1841 His father, a chemist and earnest churchman, with a deep belief in the value of educational culture, sent his son early to London University, where he graduated in 1860 before entering on a course of medicine at King's College He took the senior Warneford Scholarship, graduated in medicine in 1866, qualifying for the gold medal in the M D a year later He commenced the study of mental diseases at Colney Hatch Asylum, then under the superintendence of Dr Edgar Sheppard, grandfather of the late rector of St Martin-in-the-Fields Later he was appointed to direct the Leavesden Asylum for chronic mental cases, under the Metropolitan Asylums Board, and from there passed on to the Banstead Asylum, under the Middlesex Justices, then newly established for chronic mental disorder This intention of the founders was happily frustrated, for exigencies of space and the demand for increased accommodation soon necessitated the remodelling of Banstead for the reception of acute patients, and it was at Banstead that Claye Shaw's life's work was begun and completed He secured the confidence of the Middlesex Justices in such degree that he was invited to advise them, and later the London County Council, in the planning and construction of Claybury, the first modern asylum for London, where Sir William Collins afterwards established the first pathological laboratory for the scientific investigation of insanity It was expected that Claye Shaw would have been the first director of Claybury, but he recommended for this post Sir Robert Armstrong-Jones, electing to remain at Banstead himself

Dr Claye Shaw's contributions to the literature of mental disease were many and varied He frequently wrote for the medical papers on the newest currents of psychological thought, and his able and original pen relieved the pages of many lay journals in which he castigated the popular indulgences and fickle fashions of the day, especially upon the psychological side He had faith and courage, for he was ever hopeful of seeing an out-patient department for mental cases at St Bartholomew's Hospital, where he taught, and this hope has since been realised The Hospital Reports owe much to him, and the Abernethian Society, which was under his special patronage Some of his essays, collected as a volume under the title " Ex Cathedra " about 20 years ago, may still be read with pleasure for their broad, human interests In consultation he was precise and definite, giving the family doctor just the accurate and careful instruction he needed for the treatment of an harassing case His academic services were largely requisitioned outside the immediate surroundings of his work, for he examined in mental physiology at the University of London and for the Board of Army Medical Studies He lectured on clinical insanity at St Luke's Hospital, and occupied the chair of psychological medicine at St Bartholomew's He was an active member of the Medico-Legal and Harveian Societies, and for several years presided over the Society for the Study of Inebriety He was largely instrumental in founding the After-Care Association, which keeps in touch with mental patients after their release from institutional treatment

In early life Dr Claye Shaw was distinguished as an amateur actor Sir Robert Armstrong-Jones, to whom we are indebted for many personal details, tells us that he was extremely musical and found great pleasure in playing the organ, not long ago he contributed to the discussion in the *Times* on the healing value of music He was an authority on the subject of the stage and was a well-known member of the Garrick Club He spoke and read French and German fluently and was an admirer of the habit of thought shown in German psychology Instinctively critical and with a satirical tendency which did not permit him to suffer fools gladly, he was often regarded as antipathetic—an erroneous impression disproved by his relation to students, on whom he exerted a magnetic personality touched with a quaint and indefinable humour which never failed to kindle enthusiasm Those who attended his early ward lectures at Banstead in the eighties, when it was his custom to carry in his hand a short cane or marshal's baton to indicate authority, will not readily forget their first insight of the insane mind He was apt to raise questions of absorbing interest such as What would happen if men could live their lives again, retaining their experiences of mistakes and success, with a fair knowledge of the causes that led to them ? contending that it would be a tame world if the interest attached to what we now call chance ceased to exist He attacked the " gentle dulness " of mankind, of whose existence he was often conscious, quoting with approval Wundt's declaration that people think very little and very seldom, and he delivered a courageous lecture on the special psychology of women, reaching conclusions bearing upon the rightfulness of women's claim to the electoral franchise at a time when medical men generally hesitated to express such opinions His presidential address to the Section of Psychological Medicine at Exeter in 1907 reads now like a modern presentment of the subject, dealing as he did with the need for classification of cases in institutions and the establishment of mental clinics in connexion with the out-patient departments of general hospitals

In his social life Dr Claye Shaw was much helped by his wife, who was Hannah Gratrix, daughter of the late J Ridgway, of Leavesden, who predeceased him by two years, and who bore him two daughters, one of whom is married to a medical man

FREDERICK GEORGE LARKIN, F R C S Eng

The death of Mr F G Larkin in his 80th year removes a practitioner of wide interests and many talents He received his medical education at Guy's Hospital, where he became president of the Physical Society, and it was before this society that, in 1869, he read the paper on Nephrostomy and Excision of the Kidney, which opened his medical career so auspiciously By its originality and suggestive value, this paper aroused wide interest and is said to have led to the use at Guy's Hospital of operative measures for the treatment of renal calculus and other lesions of the kidney In recognition of this work and of the lifetime of service which followed it, Mr Larkin in 1915

Dr F G Larkin

10 per cent argyrol He thought suction was the main factor in producing improvement, and agreed with Dr Martin's account of the relief afforded by the procedure The technique was as follows The patient has the fauces and pharynx swabbed with 20 per cent novocain for five minutes, then 5 per cent cocaine is swabbed over the epiglottis and glottis The patient lies with head extended, and Jackson's bronchoscope, smeared with 1 per cent cocaine ointment, is introduced—there is generally some spasmodic cough as the tube is passed into the trachea and left bronchus—and 1 per cent cocaine is applied on a mop holder through the bronchoscope A water or electrical suction tube empties the right bronchus of pus which is generally present When pus is seen exuding from the middle lobe bronchus a sucker with spiral spring end, which can be made to enter any lateral bronchus after exit from the bronchoscope, is introduced and further pus evacuated Then removing the tubing from the sucker and connecting the latter with an irrigator, and at the same time inserting alongside of it another suction tube, the cavity is irrigated with warm boracic lotion When the patient shows signs of distress the apparatus is withdrawn, the patient sits up and coughs out the excess of fluid

The Importance of Prevention.

Mr J E H **ROBERTS** said that the advanced type of case ought not to occur ; it was a confession of the failure of early treatment Neither the surgeon nor the physician could cure advanced bronchiectasis Prophylaxis was not sufficiently considered , certain conditions were known to predispose to bronchiectasis, and patients suffering from them were turned out of hospital and not seen again until it had developed. They should be very carefully watched, and measures such as vaccines, avulsion, removal of foreign body and pneumothorax, should be carried out early When the early stages of bronchiectasis had established themselves, the physician, surgeon, radiologist, and bronchoscopist should coöperate as a team. Nearly all cases were unilateral at the beginning, when lipiodol had confirmed the diagnosis and a course of some months' treatment had proved unavailing, surgery should be called in. He agreed that phrenicotomy was not curative except in the early stages, but thought it should always be done as a preliminary to other collapsing operations It nearly always improved the patient's condition and so reduced the risk of subsequent procedures Thoracoplasty had given very good results in early cases, but failed in advanced ones, although it might be of great value as a palliative Grave consideration must be given before the dangerous operations of cauterisation, with its mortality of 20 per cent , and lobectomy, in which the mortality was 50 per cent Lobectomy was necessary in cases where there was associated sepsis beyond the limits of the bronchial tree ; these did not do well after collapsing operations The general line of treatment should be a surgical crescendo He showed slides of a case which had been cured by removal of a collar stud from the bronchus The man had been X rayed several times before, but always in his shirt and vest, and the stud had been taken for a button

Dr F. G **CHANDLER** said that non-tuberculous fibrosis was usually the result of broncho-pneumonia or whooping-cough more rarely of occupation, foreign body, or pressure When possible the cause should be dealt with, and general health must be built up to avoid infection Vaccines might be useful or very dangerous For a progressive case artificial pneumothorax was the best measure, releasing the bronchi from traction for a year or two Failing this 500–1000 c cm of oil of gomenol might be injected The treatment of bronchiectasis depended on the type, localisation, and extent The advanced bilateral basal "glove-finger" type could only be palliated ; less advanced cases improved under postural treatment, creosote and inhalation Unilateral cases could be treated by pneumothorax Phrenic avulsion was another method he preferred to try before resorting to rib-mobilisation or thoracoplasty Oil of gomenol might be tried Some cases of lung abscess cured themselves, other called for pneumothorax, but the best course was drainage, provided the pleura was or could be made adherent at the site of operation. If the walls would not approximate after drainage, phrenic avulsion should be performed Lipiodol would not enter a chronic abscess, and so formed a useful agent in differential diagnosis

In answer to a question by the President, Dr Chandler explained that gomenol was a French preparation of paraffin oil with eucalyptus in it

Exploratory Operation

Mr H S **SOUTTAR** quoted two illustrative cases The first showed the importance of excluding foreign body The patient said her troubles dated from choking on a piece of mutton bone some months before Bronchoscopy revealed a minute piece of bone in a mass of granulation tissue beneath a large abscess. Removal practically cured her. He was strongly in favour of exploration of the chest as a primary procedure It was safe and caused little trouble to the patient, and the condition of the lung could be made quite certain, if a piece of hard non-collapsible lung were encountered the production of a cavity in it by low temperature cauterisation gave the best results With due precautions the procedure was not dangerous and was certainly most effective Aspiration was most dangerous unless the pleura was known to be adherent

Mr V E. **NEGUS** described his experience of a hundred bronchoscopies ; the operation was easy and caused only four or five minutes' discomfort to the patient, who could go home alone after it It was therefore suitable for out-patients, and was at any rate worth trying first In his experience foreign bodies were rare He showed slides illustrating a case in which suppuration had been caused by a fibroma in a secondary bronchus Cure had followed its removal through the bronchoscope He also showed diagrams explaining how swelling of the bronchial mucosa in bronchiectasis upset the normal mechanism so that the bronchus was obstructed in expiration, and no amount of coughing could expel the pus For this reason he regarded dilatation and swabbing with silver nitrate as the essential parts of bronchoscopic treatment The bronchi were held open by the tube so that clear drainage was possible. The surgeon could tell at the third or fourth treatment whether or not bronchoscopy would do good The only adverse results he had known were a death after injection of lipiodol, and loss of a swab temporarily in a bronchiectatic cavity He had injected both gomenol oil and iodoform, but they had, if anything, made the patients worse

The Importance of Septic Foci in Chronic Bronchitis

Dr **GEOFFREY MARSHALL** said that the respiratory defences against infection were very good, but might be broken down by the failure of the nervous mechanism to prevent inhalation of a foreign body, by gross structural changes, and by repeated invasions of pathogenic organisms from a focus of infection outside He advocated thoracoplasty or artificial pneumothorax for pulmonary abscess The role of the pulmonary surgeon was a very limited one, but lung abscess he should certainly treat, and also a few cases of limited bronchiectasis Surgical measures caused far more chronic pulmonary disease than they controlled. The immediate results of rib resection and tube drainage for empyema were admirable, but 50 per cent of cases had some chronic lung trouble afterwards The tube should be sealed off by a watervalve even within the 24 hours He urged the importance of thorough investigation of cases of chronic bronchitis, and quoted a number of patients in whom the discovery and removal of pus in the accessory sinuses had cleared up bronchitic conditions of many years' standing Bronchitis in the upper lobes was invariably associated with sepsis in the nose, throat, or sinuses

THE TREATMENT OF NON-TUBERCULOUS INFECTION OF THE LUNGS

Discussion at the Royal Society of Medicine

A special meeting of the Sections of Medicine, Surgery, and Laryngology was held on Jan 25th, with Dr **Hugh Thursfield**, President of the Section of Medicine, in the chair when a discussion on this subject was opened by Dr. **L S T Burrell**, who dealt with

Bronchiectasis, Abscess of the Lung, and Pneumomycosis

The treatment of *bronchiectasis*, he said, must depend on its severity and must not expose the patient to greater risk than the disease A cause, such as foreign body, should be sought and removed if possible, and simple measures, such as posture and inhalation in a creosote chamber, should be tried before more elaborate methods Artificial pneumothorax was successful for unilateral disease, but usually there was too much adherent pleura to permit of collapse Phrenic avulsion had not proved valuable in his cases In expert hands good results followed aspiration and washing out the cavities through a bronchoscope Thoracoplasty should not be lightly undertaken, as the excellent results in a few cases were balanced by disappointment in the majority Drainage relieved the patient for a time Lobectomy was very dangerous, but partial lobectomy by cautery, though still in its infancy, seemed promising Pneumolysis—stripping the pleura and inserting wax or fat—had not proved very successful

Acute abscess often yielded to rest, posture, and hygiene, but after a month pneumothorax was indicated and should not be delayed lest adhesions form The lung might be re-expanded after a few weeks and collapsed again if symptoms recurred After a time it could be expanded without producing symptoms The yeast cells so often seen in the sputum came only very rarely, in Dr Burrell's opinion, from the bronchi or lung Fungi might cause lung disease with signs and symptoms like those of tuberculosis or carcinomatosis Mycelia were found in the sputum, and large doses of potassium with pneumothorax caused rapid improvement

The Surgical Treatment

Mr **A Tudor Edwards** said thatthe X ray appearance of a chronic *simple abscess* was characteristic the diagnosis should not be confirmed by aspiration unless the pleuræ were adherent, lipiodol rarely entered the cavity because of the swelling of the bronchial mucosa Of surgical measures artificial pneumothorax was more useful at an early stage, especially where the abscess was so near the hilum that drainage was made risky by the large vessels At the periphery it might break down adhesions and infect the pleura, for these cases drainage should be performed at once under local or intratracheal anæsthesia External drainage for five or six weeks was the ideal treatment, but should only be undertaken after careful X ray localisation When the pleura was free it should be rendered adherent by packing with iodine gauze four or five days before the pneumotomy The incision should be vertical to allow resection of a rib above or below if necessary, and the tract should be oblique to allow easy closure Drainage through the bronchus was rarely adequate, and repeated aspiration should be tried for an abscess near the hilum Larger abscesses gave rise to a good deal of fibrosis and secondary bronchiectasis as they healed, and phrenic avulsion was therefore needed in some cases to avoid subsequent thoracoplasty *Bronchiectatic abscess* and the communicating bronchi were clearly shown up by lipiodol, all cases should be investigated by the bronchoscope to eliminate the presence of foreign bodies Lavage was rarely satisfactory, but pneumotomy had given encouraging results It should be a more extensive procedure than for simple abscess, all pockets should be opened up and the cavity lightly packed Phrenicotomy or thoracoplasty might be required to close the cavity later

X rays and lipiodol injections were very important in the diagnosis of *bronchiectasis*, bronchoscopy should be a routine procedure Unilateral cases could be treated in several ways Artificial pneumothorax was only of permanent benefit in the very early stages and drainage had been abandoned Bronchial lavage might greatly improve or cure in many instances, and bronchostomy occasionally ameliorated the condition. Phrenic avulsion prevented the establishment of the condition after other diseases, but did not cure. Thoracoplasty gave good results, but the affected areas were sometimes too rigid to collapse Those cases which gave temporary good results with artificial pneumothorax were likely to be cured by thoracoplasty He had only tried cautery pneumectomy in two cases and lobectomy in one The latter would be the ideal procedure if the technique were improved.

Endoscopy

Mr **G Ewart Martin** said that the use of the bronchoscope was now beyond the experimental stages and had recently been much simplified He compared it with cystoscopy, and illustrated its value in two cases of foreign body which had been diagnosed as tuberculosis and bronchiectasis It caused no ill effects and required no anæsthetic save slight spraying of the epiglottis with cocaine American bronchoscopic clinics found a very much higher proportion of foreign bodies than observers in this country, and it seemed that the possibility was too often forgotten The removal of a foreign body gave a 90 per cent cure of its accompanying infections The few contra-indications to bronchoscopy were recent hæmorrhages, high fever, concurrent severe heart infections, and acute toxæmia Postural coughing would not empty cavities which could be sucked dry by the bronchoscope Cases of bronchiectasis with similar symptoms did not respond to the same type of treatment, and each case must be taken individually Mr Martin described the method he had used and the fate of the 31 cases he had treated by aspiration followed by a weak boracic wash-out. The percentage of cures was small in these chronic cases, but nine of his series had had no more trouble There had been three complete failures, and in all of these there had been multiple cavities with toxæmia. Sixteen were still under treatment and all showed marked improvement, and were strikingly grateful for the aspiration and lavage

Dr **K D Wilkinson** confined his remarks to bronchiectasis, most of which seemed to follow influenza or pneumonia in childhood Since far more cases occurred among hospital patients, it might be that infections of the teeth, tonsils, or nasal sinuses played an important part There was no definite dividing line between bronchiectasis and bronchitis, though a well-marked case could be diagnosed easily The milder cases did well as a rule The three best measures were postural drainage where this could be insisted on twice or thrice daily for long enough; creosote inhalations or Lee's drops, and vaccines He was doubtful if pneumothorax offered real hope of effective treatment He described three patients in whom the lung had been drained or cauterised, and hoped that some safe and more speedy method of dealing with the diseased lung would be devised The diagnostic value of lipiodol could not be over-estimated.

The Laryngologist's Point of View

Mr **C A S Ridout** said that his experience had been limited to chronic bronchiectases, in which he found that bronchoscopy benefited those cases in which radiography revealed a definite area in one or both lungs He described a case in which suction only was used on the earlier occasions lavage later and once the introduction of a drachm or two of

HARVEIAN SOCIETY OF LONDON.—A clinical meeting will be held at Paddington Green Children's Hospital on Thursday, Feb. 3rd, at 4.30 P.M. Tea will be served before the meeting.

ROYAL INSTITUTION.—On Tuesday, Feb. 1st, at 5.15 P.M., Prof. Julian Huxley will begin a course of six lectures on Animal Growth and Development.

HUNTERIAN SOCIETY.—The annual dinner of this Society will be held at the Hotel Victoria, Northumberland-avenue, on Thursday, Feb. 10th, at 7.15 for 7.30 P.M. The Lord Chief Justice, the Lord Mayor of London, and the Lady Mayoress will be amongst the guests.

ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.—The annual general meeting of the Association will be held to-day, Friday, Jan. 28th, at 3.30 P.M., at the Grand Hotel, Manchester. Dr. James Bennett will give an address on the Pending Changes in the Administration of Vaccination. An address by Dr. F. P. Sarjant, the President-elect, will follow.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—The annual general meeting of the Association will be held at 11, Chandos-street, Cavendish-square, W. 1, on Friday, Feb. 4th, at 5 P.M. (Tea 4.30 P.M.) Dr. James Collier will deliver an address entitled Some Personal Impressions upon the Symptomatology and Diagnosis of Poliomyelitis.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—The Thirteenth Annual Conference will be held at the British Medical Association House, Tavistock-square, London, on June 30th and July 1st. The address of the National Association is 19, Tavistock-square, W.C. 1.

ROYAL SOCIETY OF ARTS.—At a meeting of the Indian Section to be held to-day, Friday, Jan. 28th, at 4.30 P.M., an address on Forecasting and Control of Cholera Epidemics in India will be given by Sir Leonard Rogers. Sir Michael O'Dwyer, formerly Lieutenant-Governor of the Punjab, will preside.

BRITISH INDUSTRIES FAIR.—This Fair, organised by the Department of Overseas Trade, will be held at the White City, Shepherd's Bush, London, from Feb. 21st to March 4th, the Birmingham section being held at Castle Bromwich between the same dates.

RONTGEN SOCIETY.—A general meeting will be held at the British Institute of Radiology, 32, Welbeck-street, London, W., at 8.15 P.M., on Thursday, Feb. 3rd, and not on Tuesday, Feb. 1st, as was previously arranged. Dr. J. Woodburn Morison will read a paper describing the new radiological department at the Royal Infirmary, Edinburgh, and Mr. H. D. Griffith will read a paper on the Physics of Carbon Arc Therapy.

ROYAL SANITARY INSTITUTE.—A Congress will be held at Hastings from July 11th to 16th under the presidency of Sir William Joynson-Hicks, the Home Secretary. A lecture will be given by Sir William Willcox on Chronic Rheumatism in its Relation to Industry, and there will be a series of sectional meetings and conferences.

JEWISH DRAMA LEAGUE.—A dramatic reading of of "Professor Bernhardi" by Arthur Schnitzler is to be given by the League on Sunday, Feb. 13th, at the Little Theatre. The action of the play takes place in a large hospital in Vienna. Of the 22 characters 18 are doctors and one is a nurse. Tickets will be available to members only, and particulars of membership may be had from Mr. C. Landstone, 35, Cranley-gardens, Muswell Hill, London, N. 10.

THE LATE DR. J. C. UHTHOFF.—The death occurred at Bournemouth on Jan. 19th, at the age of 70, of John Caldwell Uhthoff, M.D. Lond., F.R.C.S. Eng., who was until recently one of the best-known physicians practising in Brighton and Hove, and President of the local branch of the British Medical Association. Educated at Brighton College, he studied medicine at Guy's Hospital and qualified in 1877. Two years later he graduated as M.D. Lond., and in 1881 became a Fellow of the Royal College of Surgeons. At Guy's he won a considerable reputation both in his work and as an athlete. Settling at Hove he soon acquired a large practice. Appointed physician to the Royal Sussex County Hospital and the Sussex Eye Hospital, he made a special study of diseases of the eye and became widely known as a specialist. His advice was often sought by the judges of the local county court circuit with whom he sat as assessor. About 12 years ago he took into partnership Dr. Frederick (Eric) A. S. Hutchinson, who, by tragic coincidence, died suddenly on Jan. 6th whilst on holiday in Switzerland. Dr. Uhthoff retired from practice in the summer of 1921 and went to live at Bournemouth. He was twice married. His first wife was the daughter of the late Mr. Charles King, formerly of North Lodge, Enfield, and his second a daughter of the late Mr. F. G. Cuningham, of Bentley House, Hants.

WOLVERHAMPTON HOSPITAL SATURDAY FUND.—This fund last year reached the "record" sum of £14,357, notwithstanding that the thickly populated district served by the hospital has been very hard hit by the industrial depression.

GLASGOW STUDENTS' COLLECTION FOR CHARITIES.—The annual carnival for the benefit of local charities (carried out by nearly 4000 students of the University of Glasgow) realised about £14,300, being nearly £4000 more than last year's record. Nearly £3000 of the total was realised by the sale of a special magazine, while about £8000 was collected in the form of copper coins.

GRAVESEND HOSPITAL.—This hospital has just expanded its name to "The Gravesend and North Kent Hospital." There are 70 beds and the annual statement records that the wards are "most hopelessly overcrowded and that the out-patient department is utterly inadequate." The new patients in 1926 were 21 per cent. more than in 1925, which itself was a "record" year, and enlargement has become imperative.

SPINNERS' CANCER.—At an inquest held at Oldham on a spinner, aged 78, who had died of epithelioma (mule-spinner's cancer), Dr. A. Smith said that 15 cases of spinners' cancer had passed through her hands during 18 months' experience at the Oldham Union Hospital. The verdict recorded death from epithelioma arising out of his employment.

BRADFORD MUNICIPAL HOSPITAL.—The Health Committee of Bradford Corporation has granted facilities to the workers connected with the welfare scheme of certain local firms whereby these men, by the payment of 1s. per annum to a benevolent fund, are able to insure themselves and their dependents against charges for treatment at the Municipal General Hospital. A socialist member of the Board of Guardians proposed that the Health Committee should be recommended to grant similar privileges to all who might apply, but the motion was rejected by a majority of one. The cost of running the hospital last year was £100,000, of which £52,000 was met by the Corporation and £42,000 by the Guardians, the balance being made up by patients' payments.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 1st.—5.30 P.M., ORTHOPÆDICS (Cases at 5 P.M.): Clinical Meeting. Cases will be shown. 8.30 P.M., PATHOLOGY: Laboratory meeting at the National Hospital, Queen-square, W.C. 1. Dr. D. McClean and Dr. E. O. Flynn: The Application of the Kahn Test to the Cerebro-spinal Fluid. Dr. E. Weston Hurst: The Production of Hepatic Cirrhosis by Manganese. Dr. J. G. Greenfield: The Occurrence of Hæmofuscin in Nerve Cells. Dr. E. A. Carmichael: Some Types of Cerebral Glioma. Dr. J. G. Greenfield: Hortega Cells and their Pathological Alterations. Specimens of tuberous sclerosis and diffuse sclerosis will also be shown.

WEDNESDAY.—5.30 P.M., TROPICAL DERMATOLOGY-THERAPEUTICS: Special Discussion on The Treatment of Leprosy. Speakers: Dr. J. M. H. MacLeod, Dr. J. H. Sequeira, Dr. Graham Little, Dr. G. Pernet (Dermatology), Dr. T. A. Hendry (Therapeutics), Dr. E. Muir, Dr. H. W. Wade, Dr. C. B. Lara, Sir Leonard Rogers (Tropical) and other speakers.

FRIDAY.—5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Cases will be shown by: Mr. Walter Howarth, Dr. Dan McKenzie, Mr. T. B. Layton, Mr. Herbert Tilley, Mr. N. Stuart Carruthers, Mr. Norman Patterson and others. 8.30 P.M., ANÆSTHETICS: Paper: Mr. S. P. Wilson: Physiological Bases of Hypnosis and Suggestion with Special Reference to Anæsthesia.

SATURDAY.—10.30 A.M., OTOLOGY (Cases at 9.45 A.M.): Papers: Dr. C. P. Symonds: Cerebral Abscess, some points in Diagnosis and Localisation. Dr. Farquhar Buzzard: The Treatment of Traumatic Facial Paralysis. Cases and specimens illustrating these subjects will be shown by: Mr. T. H. Just, Mr. C. Gill-Carey, Mr. R. J. Cann, Mr. W. H. Ogilvie, Mr. E. Watson-Williams, Mr. Sydney Scott, Mr. W. M. Mollison, Mr. G. W. Dawson, Mr. R. D. Owen and Mr. T. B. Layton.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Jan. 31st, to SATURDAY, Feb. 5th.—FELLOWSHIP OF MEDICINE: Special lecture at the Medical Society, 11, Chandos-street, W., at 5 P.M. on Thurs. Mr. H. W. Carson: Complications of Gall-stones.—

Collapse induration of the lung might also be cured by removal of septic foci

The PRESIDENT remarked on the change that had taken place of recent years; a little while ago the physician had implored aid from all sorts and conditions of people, and neither surgeon nor laryngologist would help him, now they blamed him for not sending these cases to them early enough He thought that the laryngologist's position was the one most likely to come to the fore, since he could form for himself a picture of the disease, which had been quite impossible up to a few years ago Washing out the dilated bronchi appeared to be a promising measure, especially for those serious conditions which sometimes might develop even in a few days

Dr E STOLKIND referred to a case, published by him in 1912, of a child who brought up stinking pus after repeated attacks of pneumonia Cauterisation was unsuccessful, and the autopsy revealed part of a horn ring at the bifurcation of a bronchus He recommended pneumothorax for chronic pneumonia

Mr TUDOR EDWARDS, in reply, said that phrenic avulsion provided permanent cure for those cases which still had fibrosis after pneumothorax and were liable to recrudescence of symptoms It was characteristic of bronchiectasis that collapse of the lung took place slowly, and would never occur at an exploratory operation He did not think Mr Souttar's case was a true bronchiectatic abscess It might be three months before the collapse was complete Phrenicotomy, together with aspiration, might cure some cases when either alone would fail He had had an empyema tube made with a flange so that a negative pressure could be set up at once

Mr MARTIN, replying, said that lipiodol could be injected into an abscess through the bronchoscope If it were introduced per os or through the cricothyroid membrane it met such a pressure of air in the trachea that the oil was broken up into tiny droplets which would stick on any little abrasion, giving the appearance of a cavity Bronchoscopic injection then gave quite a different appearance

---

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Thursday, Feb 3rd, at 5 P M, Mr H W Carson will give a lecture on Complications of Gall-stones This is the second lecture of the series on Emergencies in Medicine and Surgery A special demonstration in clinical surgery will be given by Mr H J Paterson at the London Temperance Hospital on Monday, Jan 31st, at 2 P M., and on Thursday, Feb 3rd, at 5 P M, at the Royal Westminster Ophthalmic Hospital, Mr Elmore Brewerton will speak on Non-Paralytic Squint and its Treatment At the Royal Northern Hospital on Tuesday, Feb 1st, at 3.15 P M. Dr W H McKinstry and Dr P O Ellison will give a demonstration on Laboratory Methods in Clinical Medicine All these lectures and demonstrations are open to members of the medical profession without fee On Monday, Jan 31st, St John's Hospital will begin a four weeks' course in dermatlogy Daily instruction will be given and lectures will be held on Tuesdays and Thursdays Practical pathological demonstrations can be arranged, the fees being £1 1s for the clinical course and lectures and £4 4s for the pathology The London Lock Hospital is holding a four weeks' course in Venereal Disease, from Feb. 7th to March 5th, consisting of clinical work daily in the afternoons and evenings and special lectures at intervals (fee £3 3s) On Feb 7th an all-day course in Children's Diseases will begin at the Paddington Green Hospital and the Victoria Hospital for Children (fee £3 3s) From Feb 21st to 25th the Royal Northern Hospital will hold a practitioners' course in General Medicine and Surgery, with sessions at 2 15–3 15 P M daily There is no fee for this course The Special Courses in March will include the following Diseases of the Chest, the Brompton Hospital, all day, fee £4 4s; Diseases of Children, Queen's Hospital, all day, fee £3 3s, Gynæcology Chelsea Hospital for Women, mornings and/or afternoons, fee £5 5s, Ophthalmology, Royal Eye Hospital, afternoons, fee £1 1s, Orthopædics, the Royal National Orthopædic Hospital, all day, fee £2 2s, and a practitioners' course at the London Temperance Hospital, late afternoons, fee £1 1s Practical courses in Anæsthetics and Obstetrics can be arranged and arrangements can be made for clinical assistants Syllabuses of the Special Courses, the General Course Programme, and copies of the *Post-Graduate Medical Journal*, may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

Medical News.

UNIVERSITY OF WALES —At examinations in the undermentioned subjects the following candidates have been approved —

Medicine —1924* Ann Ceinwen Evans, Florence May Wallen. 1927 Thomas Jones (Clydach)

Surgery —1926* Ann Ceinwen Evans, Thomas Jones, and Florence May Wallen 1927 One candidate satisfied the Examiners, but, in accordance with the Regulations publication of the name is withheld pending completion of the qualifying scheme for the degrees of M B, B Ch

Obstetrics and Gynæcology —1926* Thomas Jones

Obstetrics and Gynæcology —1927 Ann Ceinwen Evans, Florence May Wallen, and one other candidate

*Supplementary list

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, and ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW — The following candidates have passed in the whole or part of the Triple Qualification Examination —

FINAL EXAMINATION

Eric Alva Ynyr MacKeown, Amolak Singh Arora, Henry William Bambridge, Hector Timothy Joseph Abeyesundere, Siva Ratnam Carthegasam, Emma Hughes, Abdalla Abdel Razzak, John Hubert Sturges, Robert Jordan Ormsby, Arthur Mahavidane Kulatillake, Samuel Caller, Robert Gordon Paul, Elias George Marcus, Edward Patrick Kelly, Lucy Winifred MacDougall, Don Francis Jayamaha, Ian Gordon Sutherland Hyman Taylor, Bennet Austen Van der Gert, Robert Robertson MacGibbon, Aly Kouchouk, Harold George Hebard, Ronald Alexander Paton, Charles Frederick Schilling, Archer Wilson Dunn, Donald Ross, Owain ap Vychan Jones, Lamahewage Martin de Silva, Sarukkali Patabendige Bandulasena Gunawardena, Patrick John Bourke, and Samson Amarsairi Gunawardana

Medicine —Vishveshvar Nath, John Williams, John Hall, Orry Smedley Crowthers, Joseph Eugenius Didacus Mendis, James Thambviah Amarasingham, Abran Basil Gilston, John James Craig, Reuben Abrahams, Jayawickrema Simon Fernando, and Kripa Ram Bali

Surgery —Atal Behary Paul, Orry Smedley Crowthers, Matthew Clayton-Mitchell, John Drummond Cooper, Thomas Galbraith McIntyre, John James Craig, and Kanakkumar Dhar

Midwifery —Atal Behary Paul, Vishveshvar Nath, John Williams, James Gilchrist, John Hall, Mohamad Mahmoud Farghaly, Orry Smedley Crowthers, Matthew Clayton-Mitchell Thomas Galbraith McIntyre, Alexander Lipschitz, Jayawickrema Simon Fernando, Daniel Joseph McKenna, and Kripa Ram Bali

Medical Jurisprudence —Alexander James Pinkerton, Douglas James Campbell, Sunderdas Tulsidas Sodah, Norman Webster Laing, Reginald Andries Ferdinand Maasdorp Saunders, John Pullar Logan, William Moodie Violet Dorothy Hunter, Robert Gow McInnes, James Williamson Galloway, Ian MacGilvray Chisholm, and Nutting Stuart Fraser

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE — The second lecture on the History of Medicine will be given by Dr Charles Singer, of University College, London, at the College of Medicine, Newcastle-upon-Tyne, on Friday, Feb 11th, at 4 45 P M All medical practitioners in the neighbourhood are invited to attend

SOCIETY OF MEDICAL OFFICERS OF HEALTH —An Infant Welfare Conference is to be held at Newcastle-upon-Tyne from Feb 10th–12th under the auspices of the Society's Maternity and Child Welfare Group Dame Janet Campbell, senior medical officer to the Ministry of Health, will preside, and amongst those who will take part are Dr A F G Spinks, Dr H Glen Davison, Dr J A Stephen, Dr T Y Findlay, Mr F C Pybus, Dr Mabel G Brodie, and Mr Harvey Evers The Lord Mayor and Council will entertain the conference to luncheon on Feb 11th, and there will be visits to child welfare centres and other institutions in the neighbourhood Any practitioner wishing to attend the whole or part of the conference should communicate with Dr A F G Spinks, 20, Victoria-square, Newcastle-upon-Tyne, who is in charge of the arrangements

NATIONAL HOSPITAL, QUEEN-SQUARE —A Post-Graduate Course on Diseases of the Nervous System will be held at the hospital from Jan 31st to March 25th. It will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological demonstrations, and the fee will be 5 guineas A course of lectures on the Anatomy and Physiology of the Nervous System will be arranged if there are sufficient applicants (fee 2 guineas), and there will also be a series of clinical demonstrations, chiefly on Methods of Examination of the Nervous System (fee 2 guineas) Tickets entitling the holder to attend the out-patients' clinic only (2 guineas for three months) may be had from the Secretary, and a limited number of students can be enrolled as ward clerks Applications should be addressed to the Secretary of the Medical School, National Hospital, Queen-square, London, W C 1

Notes, Comments, and Abstracts.

THE USE OF THE SOY BEAN IN HUMAN NUTRITION

BY T R PARSONS, M A CAMB , B SC LOND ,
ASSISTANT PROFESSOR FOR MEDICAL RESEARCH, THE MCGILL UNIVERSITY CLINIC, ROYAL VICTORIA HOSPITAL, MONTREAL, CANADA

THE requirements of a diet that shall be adequate for the nutrition of human beings may be stated very concisely The food must include sufficient of a well-balanced mixture of carbohydrates and fats to provide by its oxidation all the energy required for both the internal basal processes of the body and for the external physical work that the body performs , it must contain also sufficient of such proteins as on digestion yield in appropriate proportions the amino-acids that the tissues require for the replacement of their loss during "wear and tear" and for any growth that may be taking place , and lastly, it must contain small but sufficient quantities of the vitamins and salts necessary for continued health In actual practice, of course, the diet of an individual is determined not merely by physiological considerations such as these, but also by economic considerations of the relation between the cost of various foods and his own earning capacity In recent times this sociological aspect of the problem of nutrition has claimed a certain amount of attention, and a considerable mass of useful information relative to the economic as well as to the physiological foundations of the science of dietetics has been lately collected together in a very available form by Mottram [1] It is the object of this article to supplement this information by giving similar particulars for a foodstuff that promises to rival all others not only with regard to physiological nutritive value, but also as regards economic availability

Source and Properties of the Bean

The soy bean has been known in China for thousands of years, but it is chiefly in Manchuria that its cultivation has developed during the last half century. From here it is exported in enormous quantities to China and Japan, where it plays a part in the national nutrition commensurate with that played by rice This fact in itself would suggest that the bean contains materials of very definite value for the maintenance of the human body, and this suggestion is borne out by the results of chemical analysis and physiological experiment

Chemical analysis shows that on an average the soy bean contains 35 per cent of protein, 18 per cent of fat, and some 27 per cent of water-soluble non-nitrogenous extractives which are mostly dextrins and sugars The percentage of starch is surprisingly low, amounting to only 0 5 in the ripe bean The fat is characterised by a relatively high percentage of lecithin A glance at these figures is sufficient to reveal the fact that soya is a veritable "wonder plant" for a seed of such composition would appear to constitute a foodstuff of extraordinary physiological value and completeness And feeding experiments with animals have confirmed this view

McCollum [2] states that the proteins of the soy bean are distinctly more valuable from the point of view of nutrition than are those of other legumes such as the pea, but claims that the soy bean proteins are no better than those of cereals when fed *only* in such quantities as those in which cereal proteins, on account of the large amounts of fermentable carbohydrate that grains contain, can be administered But other workers, in particular Daniels and Nichols [3] and Osborne and Mendel,[4] who have made a special study of the soy bean, have come to the conclusion that the soy bean proteins are quite exceptional among the proteins of leguminous seeds in general in being completely *adequate for* normal growth and reproduction and rearing of young The first-named authors concluded that the proteins of soya are quite as valuable as the casein of milk, and they all *point* out that the soy bean seems further to be unique among seeds in containing both fat soluble and water-soluble growth-promoting vitamins Its ash is deficient in calcium and in chlorides, and although these can be readily supplied from other sources this fact has to be borne in mind in feeding experiments in which the bean is used

Its Employment as Food

In spite of these *promising* results in animal experiments it must be admitted, however, that the attempts made up to the present to popularise the soy bean as a staple article of diet for Europeans have met with little or no success One such attempt was made in Germany during the late war but it was found that the *consumption* of the beans in quantities sufficient to supply the nutritional needs of man led to digestive disturbances and other disagreeable after-effects, so that the diet could not be tolerated for any length of time (Lüthje) [5] In these experiments the beans were served after prolonged boiling as is usually the case with other leguminous foodstuffs The reason why the Eastern peoples, who regularly consume large quantities of soya, do not experience the same disagreeable symptoms is probably that they eat the beans only after they have been subjected to a process of fermentation lasting several months, during which period the constituents that are responsible for the harmful effects are decomposed But the resulting product is not one that appeals to the general European palate At the present time, therefore, the soy bean is used in this country chiefly as a source of vegetable oils and as a cattle food The only application it finds for human nutrition is in the preparation of the condiment to *which it gives its name*

Recently however, the problem of the utilisation of the valuable constituents of soya for human food has entered on a new phase, for Berczeller, working in Vienna, has devised a special process of milling combined with fractional distillation whereby the obnoxious constituents can be removed and a meal of high nutritional value obtained This special soya meal forms a slightly yellowish flour of agreeable and appetising appearance and a faint almond-like taste It differs from the product obtained by the simple milling of the bean in its complete freedom from bitter flavour and in its capability of being stored practically indefinitely without turning rancid From the following table giving the composition of the new meal it will be seen that the nutritional value of the bean is completely retained *in the milled product* —

	Per cent in the dried flour
Raw protein	45 50
Protein soluble in pepsin-hydrochloric acid	40 75
Fat	22 38
Lecithin phosphoric acid	0 145
Non nitrogenous extractives (sugars, &c)	27 16
Ash	4 31

The meal as ordinarily obtained contains 8 97 per cent of moisture Berczeller has shown [6] that animals fed exclusively on soya products show a marked preference for this new meal over the whole untreated beans and also over ordinary soya meal, and he found further that the animals that showed the longest duration of life under his experimental conditions were those that consumed the largest quantities of the new product

Relative Cost

The problem of rendering available for human nutrition the stores of valuable materials contained in the soy bean appears thus to be solved. It remains now to consider the economic factor mentioned in the opening sentences of this article and to determine the cost of this new product as compared with that of other staple foods The price of the soy bean was quoted recently [7] at £11 2*s* 6*d* a ton in Hull From this figure we estimate the cost of the new flour as follows —

	£	*s*	*d*
Cost of one ton of soy bean in Hull	11	2	6
15 per cent loss in milling	1	13	4½
Cost of milling	4	0	11
Wholesale price per ton of soya flour	16	16	9½
Add 20 per cent for retail price	3	7	4
Retail price of soya flour per ton	20	4	1½

which works out at less than 2¼*d* a pound

Now the energy value of this flour has been found to be 4730 calories per kilo, this high value being determined mainly by the large percentage of fat that the material contains If we take 3*d* a pound as a maximum retail price we find that the cost of 1000 calories in the form of soya meal is just less than 1½*d* For comparison with this figure we quote from Mottram's tables the following data, which include all the common articles of diet that provide 1000 calories at present-day English prices at a cost less than 3*d* —

Food	Cost per 1000 cals	Food	Cost per 1000 cals
	d		*d*
Vegetable margarine	2¼	Bread, brown	2¼
Oatmeal	1½	,, germ	2½
Rice	2½	,, white	2
Wholemeal	1¼	Sugar	2¼
White flour	1¼–1½	Haricot beans	1¼
Macaroni	2½	Peas dried	2½
Spaghetti	2½		

From these figures it will at once be seen that the only serious competitor of the new product with regard *to* cheapness of calorie is furnished by haricot beans, that the soya calorie is slightly cheaper than that of wheat flour, and that it is very decidedly cheaper than the calories furnished by the other fat and carbohydrate foods from which we ordinarily supply our energy needs

When we consider soya meal from the point of view of the supply of the 30 g of biologically suitable protein that the adult human organism *requires per day* the economic

DEATHS

BAKER —On Jan 20th, at the Middlesex Hospital, A de Winter Baker, M R C S, L R C P of Dawlish Devon, aged 74

HOLMES —On Jan 17th, at The Grove, Etwall, Derby, Alfred Hewston Holmes, M D aged 69

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

An Address
ON THE
VOLUNTARY HOSPITAL AND ITS FUTURE

Delivered in the Albert Hall, Nottingham, on Jan 30th, 1927,

By R G HOGARTH, C B E, F R C S Eng,
PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION,
SENIOR SURGEON, GENERAL HOSPITAL, NOTTINGHAM

The very name of Hospital Sunday reaffirms the intimate connexion between religion and medicine which is almost as old as history itself The common link is faith Religion without faith is unthinkable Medicine without faith loses half its healing power

The Healing Power of Faith

Faith, therefore, is no new thing in medicine It was once said "He cures most in whom most have faith" The sufferer who casts his cares upon his doctor rids himself of a grievous handicap Instead of obstructing the healing influence by his doubts and fears, he becomes submissive to it and may even quicken its work Hope vanishes when faith is checked But faith in what? The choice is wide It may be faith in the bottle of medicine It may be faith in the little pill It may be faith in the healing efficiency of water, hot or cold It may be faith in the well advertised virtues of a patent medicine It may be faith in a saint, or faith in a system, or faith in a book, or faith in a revelation It may be faith in a master to whose message the ears of thousands are attuned while millions hear it not Or it may be—such are the wonders of faith—faith in some plain, humble doctor in a poor neighbourhood who for a generation has gone about his business—and the Master's—of healing, unknown beyond the short radius of his daily activities but within it respected, trusted, loved Or lastly, it may be that faith in faith itself, best understood in the churches, where the injunction, "only believe," has exercised on quiet, receptive minds a soothing influence of healing, which passes the surface comprehension of the cynic, but not the deeper understanding of the wise

And now, lest you should think that I am leading you down rather vague and misty paths, I will ask you as earnestly as I can for your active, positive faith in something which happily combines in itself many of the objects towards which faith is directed I mean, of course, that great composite and complex institution, the general hospital

If you must have personality in which to believe, you will find it there on the hospital and nursing staffs If you crave the strengthening atmosphere of place, which on the religious side you expect in shrine or temple, where is it better found than in the hospital from whose doors so many have gone forth healed and rejoicing? We do not hang our trophies on our walls, for trophies harbour dust and dust is forbidden by the modern laws of health, but the records stand and are known, and the healed give us good report among their fellows And if you desire, as who does not?—the comfort of hope to steady the shrinking of fear, from whose lips does it better proceed than from those of the doctor, who, subject himself to human infirmities, knows *too much* of pain to be niggardly of reasoned assurance and the salutary stimulus of measured encouragement?

The Ideal Hospital

Perhaps you may think it strange if I go back 400 years for a definition of the ideal hospital Yet where is there a better than Sir Thomas More's, who in his "Utopia" conceived the hospital of his ideal city state to be so well appointed that "though no man is sent thither against his will, there is no sick person in all the city that had not rather lie in the hospital than at home in his own house"

Consider what the hospitals were like when those words were written They were the refuge of the destitute and the plague-stricken At best they provided little more than a roof over the sick man's head and a mattress on which he might lie Nursing there was none, and the medical art of the time was as often a hindrance as a help to recovery Horrible contagions throve in the dark and reeking corners of the wards The idea, therefore, of a hospital, worthy of its name as a Guest House where God's sick and poor are healed, and so garnished and equipped that even the rich would rather lie there than at home, may well have seemed preposterous to More's contemporaries Even to-day it requires something of an effort to break away from current conceptions, still far too circumscribed, of the function and scope of a general hospital

The General Hospital

So I invite you to conceive of your own general hospital here in Nottingham, as the hospital of the whole community in the wide area which it serves Conceive it as the hospital, not of the poor alone, nor yet of the poor and the wide range of middle classes, but of all classes who are sick—all who care to use it, with no distinction of rich and poor That is a new interpretation of the term—"General Hospital" and, with your permission, I will develop the idea But I must guard against a dangerous misconception I am not proposing to rob the poor of the least part of the birthright bequeathed to them by a long line of magnanimous benefactors I say emphatically that, while you open the hospital door much wider to other classes, you must not close it one inch in the faces of the poor The full freedom of the general hospital to the sick poor is the very origin and foundation of the voluntary system For the poor, the healing given by the hospital must still be without money and without price. But why, if nothing but the best is good enough for the poor, should less than the best be offered to others? Thus, while still maintaining the most generous definition of the poor and their poverty, I would ask all the rest to contribute to the hospital in proportion to their means, with payments graded, not merely according to the total figure of the family income, but to the figure of its necessary expenditure, which, as you know, is usually a wholly different thing

Payment for Hospital Treatment

No new principle is here involved Payment for hospital treatment is already much more widespread than is commonly supposed A recent official report has shown that 171 provincial hospitals, of which 27 are large institutions, make some provision to meet what is well described as the insistent demand for paying beds The methods adopted vary widely. In some the payment is still disguised under the form of a thank-offering Patients are told exactly what the cost of their maintenance has been and then they are invited to give as generously as they can I will only observe that no Chancellor of the Exchequer would dream of applying such a system to the Income Tax unless he was prepared for a gigantic deficit In the hospitals it produces a useful but quite inadequate amount

You will remember the poignant question in the New Testament, when, after the healing of the ten lepers, only one returned to give thanks—"But where are the nine?" I will not say that gratitude in the hospitals is expressed in the same unsatisfactory proportion But you can well understand what happens A patient who would cheerfully pay £100 to be cured when the pain is sharp upon him begins to think, as soon as the pain is gone that perhaps he never was quite as bad as he feared, that Nature unaided might have healed him had he but left the cure to her, that £100 is a lot of money, that others are much better able to pay than he, that hospitals, advantages of a soya diet become even more striking Again, taking 3*d* a pound as the retail price of the new flour, and assuming that this as bought contains 36 per cent of protein, it is easily calculated that the cost of the daily ration of 30 g of protein is approximately ½*d* And again quoting and calculating from the data given by Mottram we give the following figures for comparison —

Food	Cost of 30 g protein	Food	Cost of 30 g protein
	d		*d*
Beef (imported)	4½–5	Milk	5½
Lamb ,,	4 –4½	Cheese	4¾
Mutton ,,	3 –5½		
		Bread, white	2½
Cod	5½	Oatmeal	1½
Haddock	5	Flour, white	1¾
Herring, fresh	2¾	Haricot beans	½
,, kippered	4½		

Again, we find that the haricot bean is the only food that can supply proteins at a cost approximating in cheapness to that of the soya meal The proteins of oatmeal cost three times and those of bread five times as much But it must be remembered that in the case of the haricot bean we have calculated the cost from that of the whole unmilled seed and also that there is no evidence that the proteins of this seed possess the unique biological value demonstrated for those of the soy bean in the experiments of Osborne and Mendel and of Daniels and Nichols already referred to It is well known that the proteins of the cereals are deficient in this respect

Conclusion

The considerations put forward in this article suggest very strongly the desirability of instituting a large-scale investigation of the possibilities of an article of diet whose introduction bids fair to constitute an even greater advance in the problem of national nutrition than was occasioned by the introduction of the potato as a staple food, and of thus providing an opportunity for the realisation of the prophecy made many years ago by Haberlandt [8] that the carbohydrate stores of the potato would ultimately come to be supplemented in the diet of at least the poorer classes by the proteins and fats provided in such abundance by the soy bean

MEDICAL INSTRUCTION FOR MISSION WORKERS

Livingstone College, in Leyton, continues its valuable work of instructing missionaries of all denominations and nationalities in the elements of healing and hygiene The lecturers teach elementary physiology and anatomy, practical medicine and surgery and tropical medicine In addition to the regular courses, which occupy nine, six, or three months, there is a four weeks' vacation course in July and three three-day courses every year on the care of health in the tropics Seventy-seven students attended during the year 1925–26, seven of these taking the full session The College paid its way except for about £35, and the receipts totalled £57 more than the year before The value of even a little sound medical training to a worker among primitive people is enormous, as anyone knows who has lived in the tropics and seen the reverence with which the natives regard a person who can cure their yaws, splint their fractures, and dress their spear-wounds The missionary societies heartily commend the work done at Livingstone, and those interested in the progress of tropical dependencies could hardly support a better object

THE PHOTOGRAPHIC ANNUAL

PHOTOGRAPHY is taking year by year an increasing place in the study of medicine Radiology is largely dependent upon it and microphotography has received a great impetus now that it is known that the photographic plate may reveal structures not appreciated by the retina A proportion of medical men and women will, no doubt, be willing to accept technical help without becoming expert themselves, but radiology and microscopy will be advanced by those who are skilled in photographic technique We have just received the sixty-second annual issue of the *British Journal Photographic Almanac*, which contains an epitome of progress during the past year both in materials and methods, together with working details of practically every photographic process with which the keen worker is likely to come in contact. The addition of a selection of the best exhibition pictures of the year, produced in photogravure, enhances the value of the almanac, which is published at 2*s* by Messrs Henry Greenwood and Co, 34, Wellington-street, London, W C 2

A BOARD OF GUARDIANS' DECISION

AT a recent meeting of the Romford Board of Guardians there was a discussion upon the recommendation of the Hospital Committee that Dr W S O'Loughlin, medical superintendent of the Oldchurch Hospital, should be allowed to place his name on the list of the Essex Insurance Committee as a panel doctor for the resident staff The Ministry of Health had been consulted and had sent particulars as to the position Mr H C Price said he thought it was only right that the superintendent should receive the fees for this work At the present time others were getting the money, while he was doing the work, and the Board had to find the drugs for nothing Under the new proposal the guardians would be none the worse off and the doctor would be a little better off, while they would also be paid for their drugs Mr W H Goodchild expressed the opinion that as the doctor was a whole-time officer the money received in respect of panel patients should go into the Guardians' exchequer, and he proposed that this be done Mr J A Parrish seconded The Chairman, Mr E G Bratchett, thought Dr O'Loughlin should have the fees They could not compel him to do the work After further discussion it was decided that the guardians should have the fees

BAY MOUNT, PAIGNTON

THE Fourth Annual Report (1925) of this institution for the cure of alcoholics, drug addicts, and neurasthenics shows that Dr Stanford Park's energy and initiative are bearing fruit Bay Mount was designed only for seven patients to ensure the fullest possible individual attention, but so many suitable patients were turned away that in 1925 an annexe was built for seven more, and the medical and nursing staffs were increased The home was, therefore, able to admit 37 new patients in the year All but four were men. Twenty-six were alcoholic cases, four were drug-takers, four neurasthenic, and three addicted to both drink and drugs. Sixteen had been in homes before Defining "cure" as the removal of all alcoholic craving so that it will not return unless stimulated by alcohol, Dr Park claims to have cured in 1925 91 per cent of the patients classed on admission as probably curable, and 47 per cent of those classed as probably incurable Even old chronic cases who only came to be "patched up" have given very good results The medicinal treatment consists of hypodermic injections combined with bitter tonics every two hours Dr Park has no faith in the atropine method and is giving more and more attention to the psychological aspect and to providing occupation and interest for each individual patient All the neurasthenics and five out of the seven drug cases did well Elderly drug addicts suffer little, it is found, during reduction, but tend to manifest great sexual excitement and loss of emotional control afterwards

DOGS AND RESEARCH

THE Royal Society for the Prevention of Cruelty to Animals allows itself occasionally a vivacity of propaganda which is too much for some of its more reasonable supporters It is now exploiting to the full the conviction of a man at Bow-street last November for feloniously receiving two Irish terriers, though it is not able to congratulate itself upon the success of subsequent and similar proceedings against a member of the University College staff A photograph of the two terriers now appears upon a leaflet circulated by the Society as an invitation for signatures to a petition to Parliament for the grant of facilities for the passing of the Dogs' Protection Bill The leaflet is headed "Dogs Stolen for Physiological Research Purposes" There may be prospective signatories whom this leaflet will persuade to believe that research workers take an active interest in violating the laws of larceny It may still be worth while to reiterate that experiments upon animals are conducted only under Government licence and only by approved persons in approved places, they are subject to independent inspection by Government officials, who have reported that they are conducted with humanity, finally, they have contributed materially and at many points to the alleviation of human suffering

MANCHESTER ROYAL EYE HOSPITAL —The number of out-patients treated at the hospital during 1926 was 31,066, a decrease of 424, and of the number in-patients 2371, a decrease of 22 as compared with 1925 The average number of accidents dealt with daily was 23 hospitals, which have special difficulties of their own, must not be confounded with the problem in the provinces

And what is the secret of this happy transformation? It is due mainly to the development of various contributory schemes into which, unfortunately, I have no time to enter, to better the organisation of workmen's contributions through their voluntary levies, and to the Hospital Savings Association and to the spread of the popular Hospital Saturday and Hospital Sunday movements Not many years ago the bequests of the rich philanthropists and the annual subscriptions of the charitable were the mainstay of the hospitals They are so no longer It is not that rich benefactors give less, but that thousands of workmen now contribute their weekly pence We have had many superb individual gifts in Nottingham, but the penny beats the pound every time when it rolls in by the million, and in the large provincial hospitals the income derived from the various kinds of contributory schemes is now double that of any of the four principal items of income In our own county for example, the contributions of the miners alone amounted in 1925 to £9530 Last year's returns will show, I fear, a serious falling off owing to the long stoppage in the industry, but I am confident that the Nottingham Hospital has no permanent source of income more assured and stable than that of the miners' levy

Believe me, the key word of the future is still voluntary contribution, which to my ear has a nobler and more humane sound than either tax or rate It involves, I know continuous effort on the part of a large band of voluntary workers But though hospital workers may grumble at times and wonder why they go on, when others selfishly do nothing, they have their reward, which they deeply treasure in their hearts though they may not often speak of it aloud In a rather disillusioned world unselfish enthusiasm may become increasingly difficult to kindle But the voluntary hospital, always advancing sure of its goal, producing immediate as well as distant results, cheerful amidst suffering, mending the broken, restoring the rhythm of life to the sick, helpful always and invariably sympathetic, has never lacked good and loyal friends to champion its cause. Nor will it lack them in the days to come

It is not unlikely that the friends of the voluntary hospitals have an anxious time before them in the near future in connexion with the approaching reform of the Poor-laws and the substitution of new public health committees of town and county councils for the existing boards of guardians It looks as though the voluntary hospitals may be invited—happily there is no suggestion of compulsion—to place themselves under the direction of these public health committees, which would naturally take over control of the Poor-law infirmaries, and to receive in return additional grants of public money Until the actual scheme is produced it would ill become me to pass judgment in advance, but I am bound to say that the implications are a little alarming, so far as the independence of the voluntary hospitals is concerned, and the utmost vigilance and caution will be required The freedom of the hospitals is their very life, from their freedom springs the joyous spirit which pervades them and the enthusiasm which their cause inspires

Just one more point as to the future of our Nottingham Hospital It lacks, to my mind, one thing above all for its completion, and that is a medical school and teaching staff. We have, as you know, an infant University, whose buildings are rising grandly above the old meadows of the Trent We have still to kindle among our people a proper civic and intellectual pride in that inspiriting foundation I look forward to the day when Nottingham University will possess amid its other faculties a Faculty of Medicine, and then it will need a medical school at the general hospital Do not, I beg you, consider this a matter of academic interest only. It is not so Every large general hospital should have its medical school attached No hospital fulfils its largest purpose unless it teaches as well as heals Nothing contributes more powerfully towards keeping the resident and consultant staff of a hospital up to the highest mark of efficiency than the critical eyes of a band of eager students, quick to observe the failures as well as the successes of their instructors, and for ever comparing, contrasting and asking the why and the wherefore Doctors, like other people, give their best when most on their mettle I must not enlarge on this theme on the present occasion, but I beg of you to consider it as a problem of real importance alike to Nottingham University and to the Nottingham General Hospital

I ask you to believe, and to believe whole-hearted, in the future of your general hospital Have faith in it, for it deserves your trust There is no one on its staff, in whatever capacity, who does not give the best that he or she has to give I ask you to work for its steady development along the safe, sure lines which have carried it to its present eminence, and to widen its sphere so that it may become a centre for the diffusion of medical and surgical science as well as a temple of healing Above all, let us be content with nothing but the very best for the welfare of all our people, and for the fame of the city and the county to which we are proud to belong

---

An Address

ON THE

PENDING CHANGES IN THE ADMINISTRATION OF VACCINATION.

Delivered before the Annual General Meeting of the Association of Public Vaccinators of England and Wales on Jan 28th

BY JAMES BENNETT, M R C S ENG, D P H, J P,

RETIRING PRESIDENT OF THE ASSOCIATION.

PROBABLY no Bill of our time, not even excepting those dealing with Education and National Insurance, has envisaged or encompassed so many possibilities as the suggested Poor-law Reform Bill, and in some form or other it seems certain ere long to become law.

The Rating and Valuation Bill has been passed and is now in operation By eliminating assessment it was probably an essential preliminary to the greater Bill to follow, the necessity being to meet the day-to-day financial needs of the nation as fulfilled by its rates The Government having almost noiselessly eliminated assessment is not likely to yield to the clamour of prejudiced or conservative people who have failed to notice costly overlapping in the present administration of the health services, one of which is vaccination Changes in the control of such services are among the chief objects of the Bill, and so far as vaccination is concerned they are thought by many to be long overdue The suggested alterations in its *administration*, so far as we can yet ascertain, may not be numerous but are exceedingly important to the public vaccinator His position has always been too insecure, and this has probably militated against such open advocacy of the case for vaccination as there might have been had the fear of "creating enemies in council" been less real

VACCINATION AND THE POOR-LAW

Vaccination is a purely preventive measure and has never been regarded as curative Why, then, has it for nearly a century been controlled by a body which, so far as health goes is otherwise solely concerned with cure—in spite of the fact that at the same time we have health authorities at one time entirely, and still mainly concerned with prevention? We must go back to the beginning of Poor-law and after all, were designed to be free, and that if only they were run on business lines the expenses could certainly be cut down And the result of all this hard thinking (and there is plenty of time to think in a hospital bed) is that if he gives £5 it is really all that he can afford The plain moral, I take it, is that there should be a definite contract between hospital and patient as to what the patient shall pay

A GREAT AMERICAN PAYING HOSPITAL

Let us see how they arrange these matters in some of the American hospitals Take that of Detroit, Michigan, where Mr Henry Ford has his famous motor works You will not be surprised to hear that Mr Ford and his family have built and equipped a magnificent hospital with a School of Nursing and Hygiene attached The hospital has 600 beds and an out-patient department with a daily average of 300 patients It is on a similar scale, in other words, to the Nottingham General Hospital The Ford family have spent 10 million dollars on the land, buildings and equipment, and they met the deficit on each year's working till the institution was complete They have shown, as you will agree, a princely spirit of generosity Now, waiving all claim to interest, they expect the patients who receive treatment to pay sufficient to cover current expenses The room charges for board and nursing service vary from 4½ to 8 dollars a day, according to whether the patient shares a room with others or has a private room with bath In addition, he pays from 21 to 70 dollars a week for the professional services of physician or surgeon according to the nature of his case, and there are other charges for X ray or radium treatment and for special nursing if required Even the out-patient department makes a first visit charge of 5 dollars for the routine physical examination and 5 dollars for the routine laboratory examination, and other charges are made at subsequent visits, according to treatment

So it is clear that the Ford Hospital at Detroit is specially designed for the patient who can pay, and if the charges seem to us rather high, allowance must be made for the high wages and salaries of the United States, while if interest had to be paid on capital expenditure, the charges would be much higher still One half of the beds, 300 out of 600, are of the more expensive kind, with baths attached, at 8 dollars or 32*s* a day, with a minimum professional charge of £4 and a maximum charge of £12 a week

We have no hospitals like that in this country. Yet what a boon they would be to the middle classes, as offering a much needed alternative to the nursing home, which is an indispensable institution in our present system, but one which will, in my belief, eventually disappear when the transitional period is over, and the paying hospital system is fully developed For even the best of nursing homes are subject to the grave disability that they are run for profit The City of Detroit, of course, has a general hospital as well, where free treatment is offered to the poor, but the distinguishing feature of the Ford Hospital is that it is a full size hospital, equipped on the very latest lines, advertising its attractions to the sick public just as a first-class hotel might do, the crucial difference being that it is expected to return no other dividend than the improving health of its guests The Bishop of Durham some time ago complained of the modern millionaire's lack of cultural imagination, even when obeying his benevolent impulses This Ford Hospital is an effective answer to that charge, and I hope it may find many imitators

THE MIXED HOSPITAL

If you do not altogether like the idea of a hospital run for paying patients only, though not run for profit, consider the scores of hospitals in the United States, in Canada, and others in this country too, where free and paying patients are found together under the same roof The Liverpool Royal Infirmary has had five paying single wards since 1887. It displays the right principle, but fancy five paying beds for the whole of Liverpool! At Brighton there are 14 private rooms, at Colchester 12, and so on The scale is utterly and grotesquely inadequate In America the hospital exists as much for the paying as for the free patient There you find part-paying patients and whole-paying patients, and those who pay for extra comforts and extra privacy according to a fixed tariff, nor is the fact concealed that such profit as is made on the paying patients is utilised for meeting the deficit on the free wards The richer patients help to carry the poorer, which surely is just as it should be They share all the incomparable advantages of a great hospital, which money cannot buy outside, and they are glad to help the poorer sufferers in the adjoining wards Such a system is conceived in the true spirit of human fellowship in suffering, and, believe me, differences of class count for very little amid the stark realities of the operating table or in the hospital ward

In my view we are ripe in this country for a rapid development of this system of mixed hospitals with paying and non-paying wards, or, if it is preferred, for a system of twin-hospitals—the one for free and the other for paying patients The choice may often be determined by the possibilities of structural alterations on the existing hospital sites Moreover, hospital experts now favour the view that a maximum of 600 beds is quite enough—or more than enough—for any general hospital, and that the model hospital of the future may be a large central building for urgent cases, with a ring of branch pavilions on the outskirts of the city, to which cases may be cleared as soon as they can be moved The motor car has made changes possible which 20 years ago would have been quite out of the question

THE VOLUNTARY SYSTEM JUDGED BY RESULTS

You will say, "What about finance?" I reply that such hospitals as I have described can be financed as our existing hospitals are financed—namely, by the voluntary subscriber But he must be organised as never before It must be brought home to every man and woman that if it is their misfortune to become hospital cases their place is in the hospital When once people realise that when they are gravely ill their chance of making rapid recovery is immeasurably greater in the hospital ward, they will not withold their support Given a liberal supply of paying wards, their subscriptions, when in health, will be sure, and in time of trouble they will gladly pay the tariff charged We have to make the hospital to that extent a business proposition, just as at present the nursing home is a business proposition But it will not be run for private profit, and that, I repeat, makes the all essential difference

May I remind you, in connexion with this problem of finance, that the provincial hospitals, as was shown by the last report of the Joint Council of the Order of St John and the British Red Cross Society, are now doing remarkably well Seventy-five per cent of 750 hospitals had a credit balance of their maintenance accounts for 1925, and their invested funds showed an increase of six millions in the last five years

It is not a failing or a decaying system which can produce results like those Remember, too, that 90 per cent of the current expenditure is subscribed voluntarily, and only 10 per cent is derived from public funds in return for services, which the State or the public authorities could not render half so cheaply, even if they could do it as well Let us get rid of the erroneous idea that the provincial hospitals live from hand to mouth under the threat of an ever-impending bankruptcy It is not true They were, indeed, in a parlous financial state after four years of war, during which they had most brilliantly justified their title to popular confidence and support But that nightmare has passed away, and whenever you have a capable board of management, you find the local general hospital facing the future with a cheerful serenity The problem of the great London

BLACKWATER FEVER IN LONDON

A CRITICAL STUDY.

BY PHILIP MANSON-BAHR, D S O , M D CAMB
F R C P. LOND ,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES ,
AND
EDWARD G SAYERS, M B , CH B (N Z),
LATE HOUSE PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES

To the medical practitioner unfamiliar with the more dramatic diseases of the tropics it may be a matter of comment that such an essentially tropical condition as blackwater fever may occur not uncommonly in England in those who have recently resided in endemic areas of this disease It therefore occurred to us that an analysis of some fourteen cases of blackwater which have developed in London, and which have been studied during the last seven years, might reveal certain important aspects of the ætiology of this mysterious disease Though the admirable recent work of J. G. Thomson [1] has cleared up many hitherto unappreciated aspects of blackwater fever, it is generally admitted that there are many obscure points which still require elucidation

All the cases in this series have come from that notorious home of blackwater fever—the dark continent of Africa, especially the West Coast, where the subtertian form of malaria predominates (Macfie and Ingram) [2] All our cases occurred in Europeans of pure descent

The distribution of cases in our series is as follows. Nigeria (N & S), 6; Gold Coast, 3; Belgian Congo, 2 , Kenya Colony, 2; N Rhodesia 1 , total, 14 cases

The length of residence in the endemic area has been already dealt with by Stephens [3] and Thomson; the latter has pointed out that the chances of developing it are in direct relation to the length of time during which the individual has been exposed to the infection In our series the length of stay in the endemic area was stated in 11 cases, and varied from one to five years. the average time being 3 2 years

The next point investigated was the length of time which had elapsed from the time of the patients' arrival in England to the onset of blackwater fever In one case it developed on the day of arrival, but in no case did blackwater occur after *ten weeks'* residence the average time being four weeks The moral to be drawn from this would seem to be that patients suffering from subtertian malaria should be observed with great care during the first three months subsequent to their return to the English climate; only by this means can the danger of blackwater fever be averted To put it shortly, the reacclimatisation period is the period of danger We have been unable to elicit any factor of importance in the previous medical history of these cases, save that antecedent syphilis seems to play no part, as has been suggested in the rather analogous instance of paroxysmal hæmoglobinuria The Wassermann reaction was performed in five instances before the onset of blackwater with negative results A previous alcoholic history plays little or no part as a precipitating factor and in one case only of our series was there a definite history of alcoholic excess This case was fatal

With regard to the sex distribution 10 of the cases were males and four females Considering the relative proportions of the sexes in the tropics, especially in Africa this would indicate about an equal susceptibility of the sexes

No age appears to be exempt from blackwater, those of our cases ranging from 3½ to 62 years The subjoined table shows the incidence in different decades —

Age	Cases	Age	Cases
Under 20	1	40–50	2
20–30	7	50–60	0
30–40	3	60–70	1

The case of 3½ years, although not the youngest on record, is probably the youngest recorded in this country, and therefore is sufficiently juvenile to be of interest The mortality of blackwater in our series was exactly 50 per cent; this compares unfavourably with the average of 23 5 per cent worked out by Thomson in over 1000 cases in Rhodesia Half of our deaths occurred in adults in the prime of life and in the third decade

According to our figures, blackwater fever can occur in susceptible subjects in this country at almost any month of the year

The incidence was as follows January, 1 case; February, 1 , March, 2 , April, 1 : May, 1 : July, 1 ; August, 3 · September 1 ; November 3 No cases in June, October, or December There appears, therefore, to be no predilection for any particular time of the year.

In two instances there was a definite history of previous attacks of hæmoglobinuria In one there were two attacks within the last four years and to the third, during which he came under our notice, he succumbed A second case had suffered from an attack two years previously and he recovered. In another fatal case it is noteworthy that three brothers of the same family all fell victims to the same disease

The relationship of hæmoglobinuria to malaria was carefully investigated, and our findings are in entire agreement with those of Thomson We have divided our evidence into three headings —

(*a*) *Endemic area* —In every case the patient came from an area which has been abundantly proved to be an endemic focus of *subtertian malaria*.

(*b*) *Clinical history of subtertian malaria* was present in every case; that is to say low fever accompanied by bilious vomiting and general malaise, and that general subicteric tinge of the skin and sclerotics which stamps the malarial cachectic The dyspeptic symptoms may so dominate the clinical picture that, as in one of our cases, a tentative diagnosis of gastric ulcer had been made

(*c*) *Parasite findings* —Subtertian malaria parasite in the ring stage were demonstrated in 50 per cent. of the cases Crescents were found only once *Considering that many of these cases of blackwater* came under observation only after hæmoglobinuria had commenced, this is by no means a low proportion Thomson has pointed out the rapidity with which these malaria parasites disappear from the peripheral blood The following table correlates the parasite findings with the day of the disease :—

Before onset of blackwater				After onset of blackwater							
Day of disease	Cases exam	St P	Pa A	Day of disease	Cases exam	St P	Pa A	Day of disease	Cases exam	St P	Pa A
11	1	1	—	1	6	2	4	4	2	—	2
2	2	1	1	2	7	1	6	6	1	—	1
1	3	2	1	3	2	—	2	8	1	1	—

St P = Subtertian present Pa A. = Parasites absent

This table clearly shows that, although in the majority of cases the parasites are wholly destroyed with the onset of blackwater, and frequently with the result that the infection is extirpated this is not necessarily always so In one case in which no parasites could be demonstrated on admission to hospital, a scanty infection of subtertian rings was found on the eighth day, after the urine had become clear for about six days In other words a relapse of malaria had taken place during convalescence

Quinine in Blackwater Fever

In its more recent aspects the relationship of quinine to blackwater fever has been studied most accurately by Thomson This observer has stated that he has never seen a single case of blackwater health work to find the reason for this anomaly, which is, in fact, purely accidental

In 1834 the Poor-law Amendment Act was passed, and four years later came the Registration Act (Births, Marriages and Deaths) and the appointment of Poor-law officers At this time vaccination had survived the criticism of its earliest antagonists and scoffers Jenner had received the thanks of the nation in words and in cash, and had been honoured in many foreign countries, the evidence that small-pox could easily be prevented was obvious, and people who could afford to pay were asking for vaccination It is little wonder, therefore, that at this time the Poor-law Commissioners gave authority for Poor-law medical officers to vaccinate the poor at the public expense (1840), for not until 1848 was the first Public Health Act passed, and in 1840 the only local authorities which covered the whole country were those now known to us as boards of guardians Having taken up this wonderful discovery of Jenner's they administered it with such success that in 1854 so-called "compulsory vaccination" became law—not, however, being enforced till after the devastating pandemic of small-pox in 1871-72 Vaccination had been handled so well by the boards of guardians that it does not seem to have occurred to anyone that in the great Public Health Act of 1875 it should be transferred to the public health authorities With the introduction of the Infectious Diseases (Notification) Act of 1889, the change-over might conveniently have been made, but vaccination remains what it was at first, the only part of the boards of guardians' work which is concerned with the prevention of disease

The relationship between public vaccinators and their boards have, with few exceptions, been very cordial, and little criticism of the boards has been needed on this score The actions, however, of many boards for a number of years on the general question of vaccination may be severely criticised, for they are actions from which the country is now suffering severely by the recrudescence of preventable small-pox

CONTROL BY COUNTY COUNCILS AND BOROUGHS

It is suggested that county boroughs and county councils should take up the reins of vaccination, and this is, indeed, believed to be the essence of the change in the administration of vaccination contemplated in the new Bill

So far as the public vaccinator is concerned the machine runs so smoothly—and, according to reports from the Government Lymph Establishment, so successfully—that no single nut or bolt seems to need changing The working machinery of vaccination is all right, but the "order" department of vaccination is too often lacking in vim As regards the traveller for vaccination—the vaccination officer—it would often seem that the slacker he is the better pleased are the guardians Vaccination therefore flags Would it be different under health committees? I think it would, for such committees have the preservation of health, rather than the relief of poverty and sickness, as their main plank, and there would at least be one medical man associated with them to stand by vaccination and the public vaccinator

To get the right perspective it should be helpful to look at the matter from the point of view of the medical officer of health As to the views of the county M O H I cannot speak, but on the views of the urban and rural M O H I am, perhaps, in a privileged position, as I am public vaccinator to a county borough and a rural (county) area and M O H. to two urban and one rural district

As a district M O H I should be heartily glad, on small-pox breaking out, to be in a position to call up assistance for vaccination directly through the county M O H, thus avoiding the delay inevitably involved in getting into touch with the clerk to the guardians in order that he in turn may communicate with the public vaccinator If it is found essential to open vaccination stations the delay is added to by the fact that the clerk must (at the worst) wait for a meeting of his board, or (at the best) of a subcommittee of that board, in order to obtain sanction for opening these stations The Vaccination Order of 1917 empowers medical officers of health to vaccinate immediate small-pox contacts in case of emergency, but does not go so far as to empower them to vaccinate the numerous other people who request immediate vaccination or revaccination That is the work of the public vaccinator Delays would be enormously lessened if all that was necessary was a message to the county M O H, who would already have been given executive powers by his council for cases of emergency

OBJECTIONS TO THE TRANSFER

There are several questions, however, which it is necessary to study before willingly committing ourselves to transference to other control. First, will the power of the vaccination officer be in any way diminished or will he be given encouragement—instead of the too frequent discouragement—to utilise the powers already nominally vested in him? Secondly, will the placing of control in the hands of county boroughs and county councils mean that vaccination will eventually drift into the hands of assistant medical officers of health?

It is almost impossible for greater powers to be granted to the vaccination officer, seeing that at present he is expected to prosecute all who fail to arrange for the vaccination of children for whom they are responsible, and have not otherwise protected themselves in law This the vaccination officer can do without obtaining the sanction of his board in any particular case

But how often nowadays is a prosecution instituted? Seldom or never Largely by the opposition of ill-informed or only partly informed guardians the vaccination officer is discouraged from taking any action Could he more adequately fulfil his duties if he were under a county or borough council? I am of opinion that he could, for such councils—and perhaps more particularly county councils—would not be swayed by biased opinions in the same way that members of boards of guardians may be.

To turn to the second question, if it were likely that vaccination would drift entirely into the hands of assistant medical officers of health it would be a most serious thing, not only for the public vaccinator, but for the whole cause of vaccination In this eventuality the public vaccinator, as a separate entity—except in sparsely populated rural and in some cases urban areas—would be wiped out, and the cause of vaccination would suffer greatly from the fact that frequent changes of the assistant medical officers of health would prevent that good feeling between parents and the vaccinator which can only be developed by the passage of time, and by which the public vaccinator comes to be regarded in the same light, for this particular purpose, as is the regular medical attendant The fact that this homely atmosphere is absolutely essential to the smooth working of vaccination would surely be apparent, at any rate to the county borough M O H, who advises his committee As the change is not likely to be made in county areas, owing to the fact that assistant medical officers ordinarily live too far away from the homes of the people to be of any service, it does not seem likely that vaccination can ever drift into the hands of any other than practitioners residing in or near their appointed areas as at present

SUMMARY

I have endeavoured to put the case both for and against the proposal to remove vaccination from the control of boards of guardians and make it over into the hands of county boroughs and county councils It would apparently be to the advantage of the public vaccinator if such a transfer were made, and the change would probably be welcomed by all district medical officers of health, and, in my opinion—though this remains to be seen—by all county medical officers of health

Urine.

Observations on Urine before Onset of Blackwater.—Minute observations of the urine were made only in two cases before the onset of blackwater. In one the only abnormality detected was a trace of albumin two hours before the onset of blackwater. In the other cases, one day before the urine was quite normal, and the next morning—i.e., six hours before the onset of blackwater—urobilin and urobilinogen were present: albumin and a few granular casts were also noted.

Time of onset of blackwater was, as a rule, in the early morning, about 2 A.M.

Duration of Hæmoglobinuria.—This varies considerably. In cases which either recovered, or died after hæmoglobinuria had ceased, the shortest time was 24 hours and the longest four days. The average duration was 2 8 days In one case the urine cleared after two days, remained clear for two days, and was again pink for 24 hours.

Suppression of Urine in Blackwater Fever.—It is usually stated that the gravest danger to be apprehended in blackwater fever is suppression of urine In our series of cases suppression was not a marked feature. One case had absolute suppression for 30 hours, but recovered entirely from the urinary condition, only to die later of pneumonia. Another fulminating case passed only 2 oz. of urine in the 24 hours before death, but the fatal issue was due more to the profound anæmia than to the suppression. In at least six cases *polyuria* was noted, both during the hæmoglobinuria and in some cases afterwards Amounts up to 124 oz. in the 24 hours were noted In no case had we any reason to suspect that permanent kidney damage resulted. The results of spectroscopic examination of the urine are recorded in five cases. In two there was oxyhæmoglobin only: in one case methæmoglobin only and in two cases both pigments were present. In future, in order to see whether the nature of the pigments bears out the work of Baker and Dodds, more accurate observation on the reaction of urine in the different stages of blackwater will have to be made, and the results correlated with the pigment findings Bile, as has been frequently stated in text-books, was never found in the urine.

Examination of the Blood.

The observations on the blood are in agreement with those of other observers Before the blackwater attacks the blood picture is that of a severe case of subtertian malaria. The greatest destruction of red blood corpuscles with ultimate recovery of the patient was a young man, in whom the red cells dropped to under one million and the hæmoglobin was at one time 10 per cent A simple clinical observation regarding the presence of hæmoglobinæmia has been made in several cases At the commencement of hæmoglobinuria it will be found that the percentage of hæmoglobin is relatively high in comparison with the number of red cells. For instance, one case on the second day had 2,300 0000 red cells and 70 per cent. hæmoglobin—a colour-index of 1 5: five days later the red cells were 2 500 000 and the hæmoglobin percentage 40—a colour-index of 0 8 We suggest that the high percentage of hæmoglobin in the first instance is explained by the presence of free hæmoglobin in the serum. The number of subtertian parasites present in the peripheral blood varied greatly in different cases as has already been observed. In one only that was a fatal case were they extremely numerous A count revealed 1590 subtertian rings per c mm of blood some 12 hours before the advent of hæmoglobinuria.

Modes of Death.—We have already mentioned that none of our cases died of suppression. One died of septic parotitis following blackwater, one of acute cardiac failure, four of acute hæmolysis, and one of pneumonia Those who died of acute hæmolysis were cases of blackwater of a fulminating character and death supervened in two within 14 hours of onset

Treatment.

Treatment of Patient in Pre-blackwater Stage.—The essential difficulty which the physician experiences when confronted with a severe case of subtertian malaria is, on the one hand, the necessity of energetic treatment of the malarial infection, sometimes in order to save the patient's life: on the other hand, the ever-present danger of precipitating blackwater fever. In effect he is "between the devil of subtertian malaria and the deep, dark sea of blackwater fever."

We do not intend to discuss the minor points of treatment, but to lay down some broad principles.

(1) If, as has been shown, quinine in subtertian malaria induces hæmolysis it is reasonable to suppose that the smaller the quantity of quinine administered, the less will be the subsequent hæmolysis. Thus, there is every reason for commencing the specific treatment of subtertian malaria cases with small and repeated doses of quinine such as 1 gr. at four-hourly intervals, and gradually increasing as tolerance is established.

(2) Every precaution should be taken against chill.

(3) As both clinical and experimental work goes to prove that suppression of urine is much less likely to occur if the urine is alkaline massive doses of potassium citrate either alone or together with sodium bicarbonate should be given until the urine is alkaline. In most cases oral administration will suffice.

As a rule, in blackwater fever the urine is strongly acid, so that massive doses (it may be given in doses of 1 drachm at four-hourly intervals) are required to overcome the acidity. We do not suggest that this will necessarily stay off the onset of blackwater fever, but that it will guard against the possibility of suppression Incidentally, it is claimed by Sinton[5] that the efficacy of quinine is enhanced by the simultaneous exhibition of alkali.

Treatment of Patient during Hæmoglobinuria.—(1) If the urine is not made alkaline, as above intravenous injections of sodium bicarbonate (gr. 150 to 1 pint of distilled water) should be administered without delay. We have employed the same technique as Hanschell.[6] We consider that this is a more rational procedure than the massive injection of normal saline hitherto practised. It is not advisable ever to inject more than one pint of fluid at a time owing to the very real danger of œdema of the lungs.

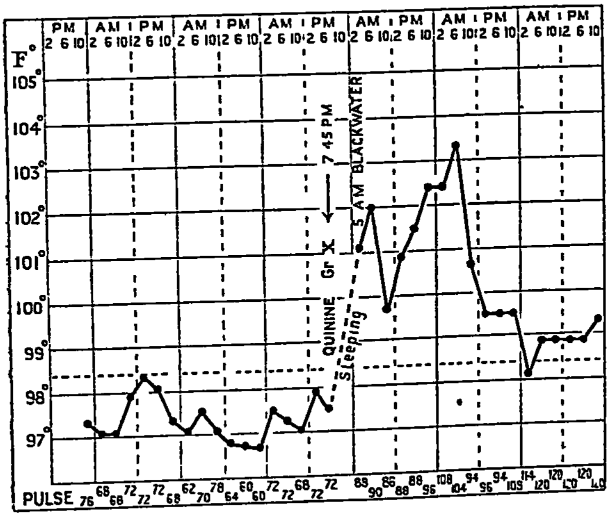
(2) Regarding the administration of quinine when once blackwater has commenced, we are of the opinion from a study of the cases in our series, as well as from a study of the literature, that there is no evidence that the continued administration of quinine has any appreciable effect on the course of the disease. It certainly does not prolong the hæmoglobinuria. On the other hand in most cases there is no indication for the exhibition of the drug as malarial parasites are usually absent after the onset.

(3) The obvious remedy that comes to one's mind in a case of severe hæmolysis is transfusion of blood from a suitable donor. There has been considerable hesitation in the past about adopting this procedure, because of the not unnatural fear of causing further hæmolysis with resulting suppression In a recent moribund case in whom the urine had cleared but who was suffering from extreme anæmia (the blood count showing only 850,000 red cells per c.mm.) blood transfusion of 700 c cm. of blood was performed, with the result that the patient revived in a miraculous manner and regained consciousness. There was no evidence of any further hæmolysis, and the urine remained clear. Unfortunately the improvement was not maintained and, in spite of a further transfusion, the patient died three days later.

Although a fatal issue ensued in this unfortunate case, we consider the results very encouraging, and have every intention of repeating it should a further occasion arise in a person who had taken 5 gr of prophylactic quinine daily We are unable to substantiate this statement in its entirety For we have accurate histories of two cases who faithfully took 5 gr of quinine daily during their stay in Africa and also during the voyage to England Another case (the brother of a doctor practising in Africa) had regularly taken prophylactic quinine, according to Koch's week-end system (i e, gr xv on Saturdays and Sundays with sodium sulph), and the child which we record, aged 3½ years, had been given 2 gr of quinine daily since leaving the endemic area and during her stay of two months in England

Effect of Quinine in Precipitating the Attack.—Anyone who has studied this subject admits the difficulty in determining the exact rôle played by quinine in precipitating the actual attack We consider it indisputable from general evidence that blackwater can occur when quinine has not been exhibited, but in our particular series it is difficult to escape the conclusion that this drug is a potent factor in precipitating the crisis In all cases, save one, quinine had been given in some form or other just prior to the attack, and not always in massive doses (from 5 to 28 gr daily) We will content ourselves with quoting one striking case —

A lady was invalided from Nigeria with symptoms of vomiting and dyspepsia, on which a diagnosis of gastric ulcer was based Accordingly she was admitted to a nursing home for X ray investigation of the intestinal tract On examination it was noted that the spleen was enlarged and she had an icteric tinge, and it was considered obvious that the gastro-intestinal symptoms were attributable to subtertian malaria No parasites were found in the blood After being in bed for four days with normal temperature the patient was given at 7 45 P M 10 gr of quinine, after which she spent a comfortable night until 2 A M when she woke up vomiting bile-stained fluid At 5 A M she had a rigor with a temperature of 101° F and passed blackwater, by 10 A M she was deeply jaundiced From a perusal of attached chart it is difficult to escape the inference that quinine precipitated this attack of blackwater



Other Precipitating Factors.

Naturally one considers the effect of chill—as in the analogous condition of paroxysmal hæmoglobinuria in which it is so well recognised In one case the onset was distinctly traceable to a thorough drenching while fishing One of our lady patients developed blackwater at the theatre at 11 P M, and we have another curious instance of a patient who, after 10 days' treatment in bed with full doses of quinine developed blackwater the morning following the first day out of doors In this case one is naturally suspicious of a chill having been the deciding factor

Clinical Aspects

In six cases of this series we have observed a condition which one may term the "pre-blackwater fever state" In three out of six seen before the onset the probability of blackwater supervening was definitely aroused in one's mind and the patient warned accordingly The following is a summary of the typical pre-blackwater symptoms low fever, nausea and vomiting, anæmia, persistent headache, constipation, general malaise, sometimes rigors The spleen is enlarged and painful, and sometimes the liver as well The urine before the attack shows a trace of albumin and urobilin It should be emphasised, however, that in some cases no pre-blackwater condition can be recognised The attack comes like a bolt from the blue as in the case of the lady already quoted in detail, a similar history was obtainable in other cases

Subjective Symptoms observed in Blackwater Fever—In 13 cases the onset was with a rigor In every case pyrexia was noted, varying greatly in height and persistency It was noted that the pyrexia frequently outlasted the hæmoglobinuria The pyrexia and rigors do not seem to be due to the effect of malaria parasites as few or none of these organisms can be demonstrated, and the temperature is entirely unaffected by quinine Undoubtedly these symptoms are attributable to the sudden liberation of the products of hæmolysis Bayliss has shown that hæmoglobin itself is not a toxic body, and the symptoms can be attributed to the stroma of the disintegrated blood corpuscles acting as a foreign protein The globin, when in a free state, is, moreover, also a toxic body and may play some part In other words, the symptoms are due to a form of protein shock

Pulse—We should like to make the observation which appears to us to be new that, on the whole, the pulse-rate is slow in proportion to the temperature.

Jaundice is more obvious in these cases which were destined to be fatal, but was noted in all

Bilious vomiting, always a marked feature of the disease, was noted in 11 cases

Abdominal pain, due to tenderness over the liver and spleen, was frequently noted as was also loin pain, especially in the early stages

Signs of Bad Prognosis—Hiccough which was noted in two fatal cases, jactitation noted in three fatal cases, and mental phenomena, such as delirium and extreme restlessness and insomnia, not affected by big doses of ordinary hypnotics, are all of serious import Delirium is common in severe cases We content ourselves with one remarkable example —

This patient remained more or less delirious until the sixth day when in the evening he suddenly became maniacal, got out of bed, seized two bottles of medicine, struck at the sister and, seizing hold of the nurse, tried to throw her downstairs He then locked the door and drank the contents of the two bottles After one hour he was induced to unlock the door and was found lying on the bed exhausted and the pulse uncountable Death appeared imminent He slept for one hour and was delirious all night. His hæmoglobin percentage at this stage was 10 During the next few days he gradually got stronger and the mental condition slowly improved There was a recurrence of vomiting, and jaundice deepened temporarily The jaundice persisted until one month from onset of blackwater and normal mentality was not reached till about the same time Eventually the patient left quite recovered

This case illustrates the fact that, although no case of blackwater fever, however slight, is too trivial to worry about, no case is too severe to despair of

Physical Signs

The Spleen—Attention was paid to the condition of the spleen in 12 cases In each it was enlarged and tender, usually reaching to the umbilicus In one case where no statement was made, both liver and spleen were found enlarged post mortem In five cases the observation was made that, after the onset, the spleen decreased markedly in size, and by the sixth day was only just palpable In one case it was not palpable at all on the fourth day The liver was enlarged and tender in six cases, usually two fingers-breadth below the costal margin

Gall-bladder—A distended gall-bladder could, in one case, be palpated with ease during the acute attacks tend to disappear at the onset of blackwater, while the benign tertian forms are still demonstrable in the blood The significance of this observation is obvious Two instances, quoted by Schilling and Jossman and Rudolf, in therapeutic malaria of hæmoglobinuria following *P vivax* infection, are possibly merely instances of paroxysmal hæmoglobinuria in syphilitic subjects

Now it will be remembered that the subtertian parasite undergoes an entirely different cycle of development in the human body from the benign tertian and quartan In the former schizogony proceeds, not in the corpuscles of the peripheral blood but in the capillaries of the internal organs, notably the spleen We submit that, in persons who are going to develop blackwater fever a great proliferation of the subtertian parasites is proceeding within the spleen pulp, and the spleen itself is engorged and tender The number of parasites found in the peripheral blood cannot therefore be taken as a real index of the number of parasites in the spleen and liver, in other words, these organs form the home of the subtertian parasite

Hæmolysis normally occurs within the spleen pulp and the capillaries of the internal organs, and coincides with the full development of schizogony of the subtertian parasite This schizogony usually occurs very irregularly Although there is no proof of its occurrence, it is possible that in blackwater fever full development of schizogony of a very large number of parasites might be attained at the same moment. The hæmolysis in the spleen would then be extreme, and the amount of free malarial hæmolytic toxin liberated proportionately great The absorption of this sudden massive dose of malarial toxin into the general circulation then leads to general hæmolysis, the resources of the reticuloendothelial system are overtaxed, and hæmoglobinuria results

The rôle of quinine in the production of blackwater is obscure, but we suggest two possible ways in which it may act —

(1) Neave Kingsbury has shown that the administration of quinine in subtertian malaria is followed always by an increase in the serum bilirubin, which begins one hour after administration and continues for 24 hours This means to say that quinine causes definite hæmolysis of the infected red cells, and, as suggested by the same worker this increased hæmolysis might be just sufficient to precipitate the onset of blackwater—i e, the last straw which breaks the camel's back

(2) Although the reduction in the size of the spleen in malaria after quinine therapy is to be ascribed to direct destruction of the parasite, there is considerable evidence that quinine can cause contraction of the spleen by a specific action on the non-striped muscle of that organ (Cushny[16]) Its action on the uterus is well recognised A sudden contraction of a heavily infected spleen, even if only of very short duration, would force a very large amount of hæmolytic toxin into the general circulation, and might thus cause a profound hæmolysis

Further work on the functions of the spleen and the effect on them of drugs, cold exercise, &c, may throw some light on the production of blackwater fever

Our best thanks are due to Dr A L Gregg, late medical superintendent, Hospital for Tropical Diseases to Dr W E Cooke, the present medical superintendent and to Dr Stuart Anderson for their care of the cases quoted in this paper, and for their assistance in making these observations

DIVERTICULITIS *

BY LIONEL R FIFIELD, F R C S ENG,
FIRST SURGICAL ASSISTANT AND DEMONSTRATOR OF ANATOMY, LONDON HOSPITAL

DIVERTICULA of the large intestine may be congenital (or true) and acquired (or false)

Garnett Wright in 1920 recorded a case of congenital diverticulum of the pelvic colon and quoted cases of Lockwood, Black, Bierhaven (quoted by Meckel), and Hedinger These diverticula are characterised by having present in their walls all the coats of the large gut—mucosa, submucosa, muscularis, and serosa —and the opening into the bowel is usually large. It is a very rare condition, for in 10,167 consecutive post-mortem examinations (at the London Hospital) not one case was observed

Acquired Diverticula Pathology

Acquired diverticula of the large intestine may be found in any part of it The commonest site is the pelvic colon, whilst above the splenic flexure and in the rectum they are relatively much less frequent Diverticula of the large intestine were present in 218 out of 10,167 consecutive post-mortem examinations —i e, 2 14 per cent —but of these 10,167 post-mortem cases, 55 per cent were less than 30 years of age, 24 per cent were between 30 and 50, and 21 per cent were over 50 In the great majority of the 218 cases the pelvic colon was the part affected, but diverticula were found in every part of the large gut, including the rectum It was interesting to note how frequently diverticula of the pelvic colon ceased suddenly at the rectosigmoidal junction They were usually multiple, sometimes numbering hundreds, but occasionally only one was present They varied in size from that of a grape to a grape seed

They were essentially hernial protrusions of the mucosa and submucosa through the circular muscle at those sites of perforation of the latter by vessels where subserous fat was present (This was first observed by Klebs) These perforating vessels occur at certain definite places (*a*) the mesocolic attachment, and (*b*) between the mesocolic tænia coli and the lateral tænia According to Hamilton Drummond, however, diverticula are prevented from passing directly into the mesocolon by the presence of the strong mesocolic tænia, so that those, following perforating vessels, appear primarily between the mesocolon and the lateral tænia Then they commonly enter the appendices epiploicæ (which lie immediately behind the lateral tænia and contain fat continuous with the retroperitoneal fat) because the fat in them offers less resistance to enlargement than does the serosa (Bland-Sutton), or pass backwards along the vessels between the serosa and the circular muscle. sometimes to lie in the mesosigmoid (Hamilton Drummond) Occasionally diverticula appear at the antimesocolic border, and then they are not usually associated with any vessels

Theory of the Genesis of Blackwater Fever based upon a Study of these Cases Correlated with Recent Biochemical Knowledge

In subtertian malaria hæmolysis occurs with each attack of fever, and in cases of "low fever," when, as so often happens, patients deny they are really ill, a chronic hæmolysis must in effect be taking place

The evidence for this is based on a consideration of the following facts —

(1) A progressive anæmia, as shown by blood counts and hæmoglobin estimations, which in subtertian infections may proceed to an extreme degree and resemble Addisonian anæmia, it is just in these cases, as one of us (P H M.-B)[7] has pointed out, that the parasites of subtertian malaria can be demonstrated only with great difficulty

(2) Indirect positive van den Bergh reactions Neave Kingsbury[8] has recently shown that in 99 per cent of cases of subtertian malaria the serum bilirubin is above the normal figure, which is taken as 0 5 units

(3) Urobilin is found in the urine in pathological amounts in 92 per cent of cases of subtertian malaria

(4) Excess of bile is excreted leading to bilious vomiting, which characrerises "bilious remittent fever" Normally the reticulo-endothelial system of the body is able to deal with the products of hæmolysis in the following manner —

The hæmoglobin is split up into (1) hæmatin (the iron-containing part), (2) globin (the iron-free protein part)

Hæmatin is not commonly found in the blood or tissues, but some observers state that they have found it in the blood in malaria, and Brown,[9] finding that solutions of hæmatin cause chills and fevers, suggests this pigment may at least be partially responsible for the symptoms of malaria

It is generally maintained that hæmatin is gradually split up by the reticulo-endothelial system into (1) an iron-free pigment hæmatoidin, or bilirubin, (2) iron-containing pigment, hæmosiderin

The bilirubin is excreted by the liver, resulting in an increased flow of bile The liver is so busy dealing with bilirubin that it is unable to deal with the urobilin, which is absorbed from the intestine, and therefore appears in the urine At the same time the amount of bilirubin in the blood is increased As long as the liver is functioning well, no bile will appear in the urine, because the renal threshold for bilirubin stands normally at four units, in fact, the threshold in hæmolytic jaundice is even higher, it being possible to have between 5 and 18 units present in the serum, without the appearance of bile in the urine This is the probable explanation of the discoloured skin and lemon-tinted sclerotics which characterise subtertian malaria

The hæmosiderin is deposited as brown or yellowish-brown granules in the liver, spleen, bone-marrow, and kidney From these sites it is later taken up to be utilised in the formation of new red blood corpuscles

The very plausible suggestion, put forward by Kingsbury, is that the enlargement of the spleen in malaria is due to the hypertrophy of the reticulo-endothelial system, in order to cope with the big demands on the system in dealing with the products of hæmolysis The extent of hæmolysis, as measured by the serum bilirubin and urinary urobilin, goes hand in hand with the size of the spleen At the onset of blackwater fever, a condition in which the hæmolysis is profound, the spleen is usually very large indeed and tender, as we have pointed out

In the majority of cases of subtertian malaria probably little or no free hæmoglobin appears in the serum But in a more severe infection, where a greater degree of hæmolysis occurs, the reticulo-endothelial system cannot deal immediately with all the products of hæmolysis, and a certain degree of hæmoglobinæmia must result.

Now, although there is hæmoglobinæmia, there is not *hæmoglobinuria*, because the kidney has a definite threshold for hæmoglobin, just as it has for sugar urea, &c, and until it reaches a certain concentration in the serum it will not be excreted by the kidney as hæmoglobin According to Pearce,[10] before the kidney will excrete hæmoglobin the blood must contain at one time more than 0 06 g of free hæmoglobin per kilo of body-weight It is also stated by Sellards and Minot[11] that at least 17 c cm. of *laked corpuscles* are necessary in order to produce hæmoglobinuria in man So it is possible to have a condition of hæmoglobinæmia without hæmoglobinuria, and doubtless this often occurs

If the hæmolysis is still more profound, then, in spite of the fact that the reticulo-endothelial system is working at its fullest capacity, some of the hæmoglobin is, as it were, "spilled over" the kidney threshold, and hæmoglobinuria, or blackwater fever results It is more a question of the rapidity of hæmolysis than of degree—i e, the red count may fall from five million to one million without hæmoglobinuria, provided that it does so at such a rate that the reticulo-endothelial system is able to deal with it A *sudden* hæmolysis of a much smaller degree, on the other hand, may temporarily overtax the powers of the reticulo-endothelial system and result in hæmoglobinuria

It is important to realise that, even when the hæmoglobinuria occurs, most of the hæmoglobin is broken up by the usual mechanism and only a relatively small proportion, 17 to 36 per cent, is excreted in the urine It therefore follows that, as is observed clinically, there is deep hæmolytic jaundice, increased excretion of bile, and the appearance of urobilin in the urine, and very obvious enlargement of the spleen

The hæmoglobin is in solution in the serum and can be demonstrated there (Thomson), but, as also was proved in one of our cases, for a short period only

According to Baker and Dodds,[12] what happens now depends on two factors (1) the reaction of the urine, (2) the concentration of sodium chloride If the reaction of the urine is above pH 6 the hæmoglobin will be excreted in the form of oxyhæmoglobin, the urine will be red and clear, and no suppression will result

If the reaction be below pH 6 and there be 1 per cent or more of sodium chloride present, brown pigment will be precipitated in the tubules The hæmoglobin passes through Bowman's membrane in dilute transudate, the reaction of which is in region of that of the blood When the tubules are reached, reabsorption and concentration take place, together with an increase in the acidity of the urine. The hæmoglobin is then precipitated—probably as hæmatin—with the result that the tubules are liable to become occluded, and renal function is impaired The urine is brown, and shows the spectrum of methæmoglobin, and there is a dense deposit The deposit seems to contain hæmatin

This explains how suppression is brought about It should be borne in mind, however, that the kidney has considerable powers of getting rid of the plugs in the tubules, as witnessed by the masses of casts found in all blackwater urines

It is noted that during blackwater fever the spleen, which at the onset is big, rapidly decreases in size, so that by the sixth to eighth day it is frequently only just palpable The explanation of this would seem to lie in the fact, demonstrated by Barcroft[13] in animals, that any condition in which oxyhæmoglobin is removed from the circulation, the spleen contracts down even to one-sixth of its original size

The crux of the question in blackwater fever is, as Sir Patrick Manson used to say "What pulls the trigger"? We consider that it is now firmly established that blackwater fever in man is found only in association with the subtertian parasite, and that reports of its association with the benign tertian parasite under natural conditions rest on slender foundation, and are probably explained by the occurrence of a double infection In these double infections, as has been pointed out by Thomson, the subtertian parasites tend to disappear at the onset of blackwater, while the benign tertian forms are still demonstrable in the blood The significance of this observation is obvious Two instances, quoted by Schilling and Jossman and Rudolf, in therapeutic malaria of hæmoglobinuria following *P vivax* infection, are possibly merely instances of paroxysmal hæmoglobinuria in syphilitic subjects

Now it will be remembered that the subtertian parasite undergoes an entirely different cycle of development in the human body from the benign tertian and quartan In the former schizogony proceeds, not in the corpuscles of the peripheral blood, but in the capillaries of the internal organs notably the spleen We submit that, in persons who are going to develop blackwater fever, a great proliferation of the subtertian parasites is proceeding within the spleen pulp, and the spleen itself is engorged and tender The number of parasites found in the peripheral blood cannot therefore be taken as a real index of the number of parasites in the spleen and liver, in other words, these organs form the home of the subtertian parasite

Hæmolysis normally occurs within the spleen pulp and the capillaries of the internal organs, and coincides with the full development of schizogony of the subtertian parasite This schizogony usually occurs very irregularly Although there is no proof of its occurrence, it is possible that in blackwater fever full development of schizogony of a very large number of parasites might be attained at the same moment The hæmolysis in the spleen would then be extreme and the amount of free malarial hæmolytic toxin liberated proportionately great The absorption of this sudden massive dose of malarial toxin into the general circulation then leads to general hæmolysis, the resources of the reticuloendothelial system are overtaxed, and hæmoglobinuria results

The rôle of quinine in the production of blackwater is obscure, but we suggest two possible ways in which it may act.—

(1) Neave Kingsbury has shown that the administration of quinine in subtertian malaria is followed always by an increase in the serum bilirubin, which begins one hour after administration and continues for 24 hours This means to say that quinine causes definite hæmolysis of the infected red cells, and, as suggested by the same worker, this increased hæmolysis might be just sufficient to precipitate the onset of blackwater—i e, the last straw which breaks the camel's back

(2) Although the reduction in the size of the spleen in malaria after quinine therapy is to be ascribed to direct destruction of the parasite, there is considerable evidence that quinine can cause contraction of the spleen by a specific action on the non-striped muscle of that organ (Cushny[16]) Its action on the uterus is well recognised A sudden contraction of a heavily infected spleen, even if only of very short duration, would force a very large amount of hæmolytic toxin into the general circulation, and might thus cause a profound hæmolysis

Further work on the functions of the spleen and the effect on them of drugs, cold, exercise, &c may throw some light on the production of blackwater fever

Our best thanks are due to Dr A L Gregg, late medical superintendent, Hospital for Tropical Diseases, to Dr W E Cooke, the present medical superintendent, and to Dr Stuart Anderson for their care of the cases quoted in this paper, and for their assistance in making these observations

16 Cushny, A. R Text book of Pharmacology and Therapeutics, 1924, eighth edition pp 469 and 474

The wall of the diverticulum was composed of mucosa, submucosa, and serosa, and in the cases in which it had entered an epiploic appendix there was a quantity of fat beneath the serosa, and it was very easy to overlook the presence of the diverticulum In the present series a prolongation of muscle was sometimes seen in the wall of the diverticulum, but never at the apex Fæcal material was generally present in the diverticula, in one of which was a foreign body. As a result of the inadequate muscle coat, combined with the fact that the opening into the bowel is usually minute and always much smaller than the lumen of the diverticulum, fæcal material is unable to re-enter the bowel Absorption of fluid takes place, resulting in inspissation and the formation of a fæcal concretion or stercolith, containing cholesterol and calcium carbonate Pressure on the musosa, combined with the inevitably present micro-organisms, results in inflammation—i e, diverticulitis Rarely this ends in resolution, but very much more commonly in fibrosis, suppuration, or gangrene Apart from being an end-result of inflammation, gangrene may also result from vascular thrombosis Perforation of the diverticulum not infrequently occurred, leading to abscess formation or general peritonitis It is interesting to note in this connexion that a careful post-mortem examination of cases of diverticulitis with general peritonitis usually revealed the same sequence of events—first the formation of a pericolic abscess, and second the rupture of this abscess into the general peritoneal cavity

In the absence of perforation bacteria may penetrate the diverticular walls and give rise to abscess formation or general peritonitis, but much more frequently to chronic localised peritonitis and peridiverticulitis As a result of chronic localised peritonitis the pelvic colon tends to become adherent to surrounding structures, especially the bladder, small intestine, uterus, and its appendages, and the parietes, in that order of frequency If perforation occur now a fistula will be formed between the pelvic colon and the adherent viscus This bi-mucous fistula was vesicocolic in four cases and rectocolic in one No case of vesicocolic fistula has yet been reported in a female, apparently on account of the intervention of the uterus and its appendages In two cases adhesions to the small intestine produced intestinal obstruction, and this may also be caused by kinking in consequence of chronic mesosigmoiditis. It may be well to recall here that if the pedicles of an abnormally mobile omega loop are approximated by chronic inflammation of the mesosigmoid volvulus is likely to occur Intestinal obstruction may result from chronic localised peritonitis in yet another way—an inflamed diverticulum in an appendix epiploica becomes adherent, forming a band which strangulates a loop of small intestine.

Abscess formation is more frequent than general peritonitis, the reason being that by the time perforation or penetration occurs protective adhesions have usually formed, thereby limiting the suppurative process In 52 cases of diverticulitis there were 11 abscesses clinically diagnosable as such, but the majority of the cases of general peritonitis were found to have resulted from rupture of pericolic abscesses, bringing the total number of abscesses up to 17 The abscesses are often small and may remain more or less latent, but not infrequently they burst into the bladder, giving rise to a vesicocolic fistula, or into the rectum or colon discharging themselves, or into the small intestine or through the skin They may track upwards between the mesentery and the descending colon or along the outer side of the latter and form left anterior subphrenic abscesses, or they may form in the retroperitoneal tissue, surround the left kidney and point in the loin Occasionally they enter the psoas sheath, within which presumably they might spread upwards, producing subphrenic abscess and empyema, or downwards pointing in the thigh Sometimes a diverticulum in an appendix epiploica is found in a hernial sac (usually left-sided femoral) and may give rise to an abscess therein Pelvirectal abscess may have its origin in pericolic or perirectal suppuration, the result of diverticulitis

Peridiverticulitis is a condition characterised by enormous thickening of the bowel wall, so that it may measure as much as 1 inch from mucosa to serosa. As contraction of the fibrous tissue occurs stenosis of the lumen results, producing intestinal obstruction in varying degree In a typical case the macroscopic appearance was as follows The peritoneal coat was thickened and adherent to surrounding structures. There was an increase in the amount of subserous fatty tissue, especially in the appendices epiploicæ The bowel wall was greatly thickened and intersected by small abscesses and sinuses and contained diverticula in various stages of inflammation, often containing fæcal concretions Generally the mucosal surface was smooth, ulceration being absent, but when a stricture was present the mucous membrane above it was sometimes ulcerated A stricture resulting from peridiverticulitis was usually tubular The adjacent lymphatic glands were frequently enlarged Microscopically the mass was found to consist of dense fibrous tissue with areas of small round-celled infiltration, whilst in other places evidence of more acute inflammation was to be found, abscesses and diverticula in varying degrees of inflammation were seen

As one would expect in the case of long-standing chronic inflammation, carcinoma may supervene. How frequently this happens is very difficult to say, but in the Mayo Clinic 7 cases out of 27 are reported and Gant records two cases, whilst Hochenegg, Telling, Roberts, and others have also reported cases In none of the present series was there evidence of the supervention of carcinoma For the recognition of diverticula in a carcinoma Wilson advises the use of a fine glass probe, with which the fresh mucosal surface of the carcinoma is carefully examined Any area in which the probe enters the bowel wall is treated by horizontal sectioning, diverticula present being thus demonstrated Portal pyæmia with abscesses of liver may complicate diverticulitis, such a case was recorded by Whyte, whilst Foggie reported a case of systemic pyæmia, in which embolic abscesses of the lungs and brain resulted from a similar cause In the present series fat necrosis was observed in the pelvic mesocolon in one case of death from general peritonitis following perforation of a diverticulum. A similar condition occurred in Roberts's case

Ætiology

Age-incidence of Diverticula in the 218 Post-mortem Cases.

Years	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80–89	Totals
Males	1	0	2	16	33	50	23	10	135
Females	0	0	5	9	23	26	18	2	83
Totals	1	0	7	25	56	76	41	12	218

The youngest patient was aged 12, the oldest aged 86 (Ashurst reported the case of a patient aged 7, the condition being verified by operation, whilst Hartwell and Cecil's case was a patient aged 6)

In the 218 cases inflammation was present in only 5.

Age-incidence of the 52 Clinical Cases of Diverticulitis

Years	20–29	30–39	40–49	50–59	60–69	70–79
No of cases	3	5	15	10	15	4

Males were more frequently affected than females—35 out of 52 cases The youngest patient was aged 23, the oldest aged 77 About half the cases were definitely obese, a small percentage thin and wasted, whilst about a quarter of the patients alleged a recent loss of weight A history of chronic constipation was obtainable from the majority, but by no means all How important a factor constipation is in the production of diverticula is difficult to say, for against it must be considered the important and well-established fact that diverticula are more common in men and constipation is more prevalent among women

The actual cause of diverticula formation is unknown, but the following theories may be mentioned —

(*a*) Graser's . periodic mesenteric congestion.

(*b*) Sudsuki's loss of perivascular fat.

(*c*) Keith's sacculation of the large gut combined with irregular tonic contraction of the circular muscle resulted in the forcing out of diverticula at weak points

(*d*) Congenital weakness of unstriated muscular tissue throughout the body resulting under certain circumstances in the formation of diverticula In support of this it is interesting to note that in the 218 cases of diverticula found post mortem 24, or 11 per cent , were accompanied by diverticula in other hollow viscera In 9 cases there was a similar condition of the small intestine, in 9 of the bladder, in 5 of the œsophagus, and in 1 of the œsophagus and bladder Hamilton Drummond in 500 post-mortem examinations found 22 cases of diverticula In 4 of these there was a similar condition of the small intestine, and in 1 of the bladder—i e , 23 per cent —were accompanied by diverticula in other organs

(*e*) Still others regard the condition as a simple atrophic manifestation Constipation is the first event, the bowel hypertrophying in an attempt at compensation When hypertrophy has reached its limit it is succeeded by atrophy and diverticulation.

If diverticula were the result of increased intracolonic pressure only, then one might have expected to find them with some frequency above strictures This was exceptional. On the other hand, it must be remembered that most colonic strictures (excluding diverticular) are carcinomatous and therefore the condition may not be long enough in existence to allow the formation of diverticula

Whichever explanation is the correct one, the two essential factors are the same presumably as in all other herniæ (*a*) weakness, congenital or acquired, of the bowel wall , (*b*) increased intracolonic pressure, whether it be due to obstruction to the onward passage of fæces or to constipation, excessive gas formation, &c

Signs and Symptoms.

The clinical features of *acute diverticulitis* have been well described as those of acute appendicitis in the left iliac fossa. They included the usual general constitutional disturbance with elevation of temperature, pulse-rate, &c , and pain, tenderness and rigidity in the left iliac fossa with or without the presence of a lump. Sometimes these signs and symptoms were in the hypogastrium or right iliac fossa There were seven cases of acute diverticulitis (13–14 per cent), in the majority of which a diverticulum had perforated

Abscess —There were 11 cases of abscess (21 per cent), 4 were in the left iliac fossa, 1 in the left loin, 3 in Douglas's pouch, 1 in the right iliac fossa, and 2 in the right lumbar region

General peritonitis occurred in 12 cases (24 per cent), in 3 of which it complicated acute intestinal obstruction

Intestinal obstruction was generally chronic with occasional subacute attacks Now and then the condition became acute (three cases, 6–7 per cent) There were 16 cases (30 per cent.) of chronic obstruction, seven of which were associated with a palpable tumour A certain number gave a history of recurrent attacks of acute diverticulitis

Vesicocolic fistula was present in four cases (8 per cent) The patients complained of the passage of flatus and sometimes fæcal material per urethram and usually of painful and frequent micturition Excluding these four cases urinary symptoms occurred in 7 patients, in one of whom the main trouble was dysuria Another suffered from hæmaturia, his urine containing pus and *Bacilli coli* Another developed a vesicocolic fistula later One case somewhat simulated a gynæcological condition and one was discovered accidentally.

Tumour was present in 23 cases, 14 in the left iliac fossa, 4 in the hypogastrium, 2 were felt per rectum only, 1 in the right iliac fossa, and 2 in the right lumbar region In the majority of these cases the swelling was due to peri-diverticulitis, but almost as many were abscesses The typical tumour, so frequently present in the left iliac fossa, was somewhat sausage-shaped, tender, irregular, hard, deeply situated, and fixed It had a distinct tendency to vary in size This was very characteristic Apparently it was due in some cases to absorption of pus or escape of the latter through a fistula and in others to subsidence of inflammation in one part of the tumour, being followed later by an inflammatory exacerbation in another Again it was not infrequently observed that the tumour diminished markedly in size after the emptying of the bowel by an enema , in such cases fæcal impaction was doubtless the main factor in the variation

Toxæmia produced a moderate elevation of temperature and pulse-rate, and occasionally in more severe cases marked loss of weight and strength resulted Somewhat characteristic was an intermittent pyrexia, the temperature not usually rising above 101° F

Leucocytosis was frequent.

Bowels —Constipation was present in the majority, occasionally alternated with diarrhœa In eight cases blood was passed per anum The bleeding in four of these was hæmorrhoidal in origin, in one very probably diverticular, whilst in the remaining three its exact source was not determined Three patients were troubled with tenesmus Pus was passed per anum by one patient whose pelvic abscess burst into the rectum

Although clinical groupings are useful, it must be understood that they frequently overlap—e g., general peritonitis may occur in a patient who gives a history of previous attacks of acute diverticulitis and chronic obstruction, whilst chronic obstruction is frequently associated with recurrent attacks of acute diverticulitis, &c

Diagnosis

Diverticulitis must be considered a definite possibility in all patients over the age of 30 who have inflammatory trouble in the left iliac fossa, signs and symptoms suggesting carcinoma of the colon, vesicocolic fistula, or general peritonitis of unknown origin It has to be diagnosed from .—

Carcinoma —Diverticulitis may simulate carcinoma very closely and sometimes a differential diagnosis is impossible, but the following points will prove helpful in deciding between the two conditions 1 Long history of chronic constipation with attacks of abdominal pain in the left iliac fossa 2. Periodic febrile attacks 3 Persistent absence of blood from the stools (macroscopic) 4. Patients usually fat and general condition good 5 Varying size of tumour, but generally large and fixed 6 Leucocytosis

These six points are in favour of diverticulitis In addition the presence of a vesicocolic fistula, which results much more frequently from diverticulitis than from carcinoma, would suggest the former The suggestion could be confirmed by *cystoscopy*. In a case of diverticulitis there will be an area of inflammation generally most marked on the posterior wall of the bladder high up with pus coming through from time to time If the case be one of carcinoma growth will be visible.

Sigmoidoscopy is not usually helpful on account of the difficulty of passing the instrument sufficiently high up If the lower end of a smooth stricture be seen and a tumour be felt immediately above, the evidence is in favour of the inflammatory condition Another point also in favour is said to be the absence of blood from the higher part of the bowel inspected. It is usually quite impossible to see the openings of the diverticula

X ray examination is often conclusive The diverticula are best seen after the barium enema has been evacuated, the bowel then being empty, but the diverticula retaining their barium for days Sometimes a long irregular tunnel stricture is seen and is characteristic.

Hyperplastic Tuberculosis —This usually presents no great difficulty in diagnosis and is more likely to be confused with cancer of the cæcum than with anything else, whilst it so rarely affects the pelvic colon that it need hardly be considered seriously in the differential diagnosis

Actinomycosis usually affects the right iliac fossa, but sometimes the pelvic colon is the part involved There is a great tendency for it to spread to the surrounding structures, retroperitoneal tissues, and the abdominal wall. Sinuses form, the typical sulphur granules containing the ray fungus are present in the pus, and the patient wastes and goes rapidly downhill

Acute Appendicitis —The diagnosis of acute appendicitis was made four times. In three of the four cases the condition found at operation was diverticulitis of the cæcum and lower part of the ascending colon whilst in another case the pelvic colon lay in the right iliac fossa, and the perforated diverticulum was ligated and removed through the gridiron incision which had been made. In two cases the pain started in the umbilical region, and then localised in the right iliac fossa, and in one case was accompanied by hyperæsthesia. There was no previous history at all suggestive of diverticulitis, and correct diagnosis was apparently impossible.

Gynæcological Syndrome.—It is recognised that diverticulitis may mimic very closely certain gynæcological conditions—e.g., chronic salpingo-oophoritis, carcinoma of the ovary, &c. Shoemaker has emphasised this very strongly, and a routine examination of the rectum and pelvic colon has been suggested by some in all cases of pelvic disease. In one case only of the present series was there any simulation of gynæcological disease. This patient had in Douglas's pouch a hard lump which was not attached to the uterus and was not accompanied by bowel symptoms, other than lifelong constipation. She was first examined in the gynæcological department, where it was suggested that she was suffering from carcinoma of the pelvic colon, but further investigation pointed to diverticulitis, which was the condition found at operation.

Pericolitis and Sigmoiditis.—Some years ago when diverticulitis was relatively unknown, these terms were popular diagnoses. But gradually diverticulitis has replaced them, just as appendicitis has replaced perityphlitis. It is probably correct to conclude that sigmoiditis or pericolitis can occur apart from diverticulitis, that these are very rare, and from the point of view of diagnosis in practical surgery need not be considered.

Fibromatosis of the colon has been described, and one very characteristic feature is enormous thickening of the submucosa. It apparently results from infection through an ulcer and is but a modification of the very rare non-diverticular sigmoiditis.

Syphilis very rarely involves the pelvic colon, but when it does the shorter history and possibly signs of previous syphilitic trouble and the Wassermann reaction amongst other things should make the diagnosis clear.

General peritonitis from other causes. If the patient be suffering from general peritonitis when first seen, other causes of that condition, such as appendicitis, perforated duodenal or gastric ulcer should be excluded if possible. A consideration of the history and physical signs including mode of onset, type of patient, presence of a lump, and site of maximum tenderness and rigidity will often enable this to be done.

Perinephric and subphrenic suppuration occasionally result from diverticulitis, and have to be distinguished from that due to other causes by the history and physical signs.

Treatment

This will be considered under several headings.

Acute Diverticulitis.—When the diagnosis of diverticulitis is certain or probable the abdomen is opened by a left lower paramedian incision. If an inflamed diverticulum be found it should be removed; if perforated drainage is indicated. In some cases it is only possible to close a perforation by over-sewing or covering with omentum, whilst in yet other cases, including those in which general peritonitis has resulted from rupture of a pericolic abscess, suprapubic drainage is all that is possible. It is to be remembered that these patients are often poor subjects for operation and desperately ill, and therefore the minimum that is necessary to give the patient a chance should be done as quickly as possible. *Abscess.*—This should be opened and drained in the usual way.

Vesicocolic Fistula.—Laparotomy is performed and careful examination made to determine, if possible, the cause of the fistula. Any manipulation must be undertaken with extreme care to prevent the opening up of a pericolic abscess, rupture of a diverticulum, or injury to the gut. Preliminary cystoscopy and the history and physical signs will have proved helpful in excluding carcinoma. Transverse colostomy is performed. As a rule the gut need not be opened until the third or fourth day. The vesical fistula usually closes in a few weeks, and excision of the affected portion of the bowel with any necessary repair of the bladder may be undertaken in about one year's time. This two-stage operation greatly diminishes the risk of general peritonitis.

Intestinal Obstruction.—The treatment for this condition is colostomy. In certain acute cases with marked dilatation of the cæcum and small intestine a temporary valvular cæcostomy may be necessary in addition. At operation it is also very essential to decided if possible whether the condition be diverticular or carcinomatous. The character of the tumour must be considered, then the condition of the glands, peritoneum, and liver. It is sometimes absolutely impossible to decide between carcinoma and diverticulitis macroscopically, and this is undoubtedly the explanation of the disappearance of certain alleged carcinomatous tumours after colostomy. In view of this, if the tumour be not definitely carcinomatous a piece may sometimes be removed carefully for microscopic examination and the wound closed by suturing, over-sewing, or an omental graft. Excision of the affected portion of gut is always inadvisable in the presence of obstruction.

Radical treatment, if not contra-indicated by the age and condition of the patient nor by too extensive involvement of the bowel, &c., may be carried out one year later, and will consist in excision of the affected portion of the gut with end-to-end union or permanent colostomy according to the amount removed. These remarks apply to obstruction of the large bowel at the affected site. Small gut obstruction is treated along the usual lines, whether due to strangulation by an adherent epiploic appendix acting as a band, or due to kinking of a loop of intestine which has become adherent to the inflamed mass. If in the latter case the adhesions be very dense, a lateral anastomosis between the afferent and efferent loops may be indicated.

Diverticula Discovered Accidentally during Screening, and causing no Physical Signs nor Symptoms.—Provided that these patients can be supervised periodically to enable the progress of the case to be watched, they may be treated medically, the essentials being thorough daily evacuation of the bowels procured if necessary by the use of mild aperients and laxatives (liquid paraffin excellent).

Prognosis

This will depend on the condition of the patient when first seen.

General Peritonitis.—This is a very grave complication. Two out of nine patients recovered; one of the remaining seven would have done likewise, but died from pulmonary embolism on the twelfth day.

Abscess.—This is a much less serious condition. 9 out of 11 recovered and 2 died from general peritonitis (not included in the above).

Acute Diverticulitis.—The prognosis in these cases, if treated by operation, is good. Seven cases were submitted to operation and all recovered.

Intestinal Obstruction.—In *acute* obstruction the outlook is bad. These patients have sometimes suffered previously from attacks of subacute obstruction and recovered with medical treatment, so that there is a tendency for the serious nature of their present condition to be overlooked too long before receiving surgical treatment. Another danger to which they are exposed is the forcible injection of enemata, which at times has caused the rupture of a diverticulum and general peritonitis. Of the three cases of acute obstruction in the present series all had general peritonitis. One died just after admission to hospital before an operation could be performed, and the other two, who were about moribund before, died shortly after operation. In one case there was a strong smell of turpentine in the peritoneal fluid, and a ruptured diverticulum had apparently resulted from the forcible injection of a turpentine enema.

Chronic.—If colostomy be performed well above the tumour and excision, when not contra-indicated, be carried out about one year later, the prognosis is good other things being equal Of five cases treated by partial colectomy four recovered and one died This case, however included a plastic operation on the bladder and is that reported below under vesicocolic fistula

Vesicocolic Fistula—Colostomy, well above the fistula, renders the immediate prognosis very good and greatly improves the patient's chance in a radical operation later Three of the four cases have been treated by preliminary colostomy, the vesical fistula has closed and further treatment will be carried out one year after the first operation The fourth died from general peritonitis two to three weeks after a radical operation had been performed without a preliminary colostomy Spontaneous cure has been reported, but must be very rare In cases that are accidentally discovered and are not giving rise to much trouble careful medical treatment will suffice

I am indebted to the Director of the Pathological Institute at the London Hospital for much helpful advice, and to those surgeons of the London Hospital under whose care were many of the patients

THE DICK TEST

AND ACTIVE IMMUNISATION AGAINST SCARLET FEVER

BY W T BENSON, B Sc St And, M D Edin,
D P H Camb, D T M & H Lond, M R C P Edin,
MEDICAL SUPERINTENDENT, CITY HOSPITAL, EDINBURGH,
AND
G W SIMPSON, B Sc, M B, Ch B Edin,
D P H Edin & Glasg,
SENIOR RESIDENT MEDICAL OFFICER TO THE HOSPITAL

IN an endeavour to estimate the reliability of the Dick test, and the value of active immunisation of susceptible individuals against scarlet fever, the nursing staff of an infectious diseases hospital, to the wards of which are admitted annually from 1500 to 2000 odd cases of the disease, affords a particularly favourable field Here we have a group of young adults, of necessity in intimate daily contact with cases of scarlet fever in the most highly infective stage of the disease The degree of infectivity is reflected to some extent in the fact that during the past six years 70 nurses in this hospital have contracted scarlet fever whilst on duty

Preparation of Toxin

The toxic filtrate used in the early part of the work, both for testing and immunisation, was obtained from a culture of the specific hæmolytic streptococcus isolated from the throat of a scarlet fever patient in this hospital For testing purposes the filtrate was diluted to 1 in 1000 with normal saline We have to thank Prof T J Mackie, of the Bacteriology Department of the University of Edinburgh, for this preparation of toxin

The development of scarlet fever in two nurses who had given negative Dick readings with the above test toxin, led us to try a more potent preparation This latter toxin (X48) was kindly supplied by Dr R A O'Brien of Messrs Burroughs and Wellcome A dilution of 1 in 1000 was employed for the test We are also indebted to Dr O'Brien for a supply of immunising toxin (X79) The comparative toxicity of a 1 in 1000 dilution of the two filtrates, which we shall name the Edinburgh and London toxins respectively, is indicated by the Dick test results set forth in Table I

TABLE I—*Dick Test Results Obtained with the Edinburgh and London Test Toxins*

Source of toxin	In 50 scarlet fever cases				In 71 cases other than scarlet *	
	1st to 3rd day of disease		14th to 33rd day of disease		Dick pos	Dick neg
	Dick pos	Dick neg	Dick pos	Dick neg		
Edinburgh	49	1	14	36 (72%)	27 (38%)	44
London (X18, B1962)	50	0	24	26 (52%)	42 (59%)	29

* 55 cases from 1 to 10 years of age 10 cases previous history scarlet All neg Edin, 2 pos Lond

The London filtrate was apparently of higher toxin content than the Edinburgh filtrate

Technique Employed

In applying the Dick test 0 2 c cm of a 1 in 1000 dilution of toxin was injected intracutaneously into the flexor aspect of the left forearm. As a control test 0 2 c cm of diluted toxin, previously boiled for two hours, was injected intracutaneously into the flexor aspect of the right forearm Readings were noted at 8, 24, and 48 hour intervals after the application of the test An area of erythema, 10 mm or more in diameter, was read as positive, whilst a lesser area of erythema was noted as negative Where areas of erythema appeared on both arms a study of their relative size, intensity, and duration led to the differentiation of negative-pseudo and positive-combined reactions

The protective injections were administered subcutaneously about two inches above and behind the elbow, in alternate arms, at either 5-day or 14-day intervals

Dick Test Results in Nursing Staff

In Table II we have the results of the Dick test applied to 187 members of the nursing staff

TABLE II—*Dick Test Results in Nursing Staff*

Age period in years	Total tested	Dick Neg	Dick neg pseudo	Dick pos	Dick pos pseudo	Dick pos Per cent	Pseudo reactions Per cent
18–20	99	62	9	25	3	28 3	12 1
20–25	78	47	10	19	2	26 9	15 4
25 and above	10	3	4	2	1	—	—
Totals	187	112	23	46	6	27 8	15 5

The susceptibility of members of the staff to diphtheria, as indicated by 65 per cent of positive Schick readings, apparently far exceeds their liability to contract scarlet fever The lower susceptibility rate to scarlet fever, as compared with diphtheria, may, in part, be explained by the much higher percentage (35) of girls who gave a history of having suffered from scarlet fever previous to their entering hospital than from diphtheria (10)

Zingher[1] found that in groups of nurses and students 40 to 70 per cent gave positive Dick as well as positive Schick reactions On the other hand, his positive percentage for 981 individuals of a mixed population, in the 15- to 20-year age-group, was 16 8

Does One Attack of Scarlet Fever Confer a Lasting Immunity?—Of 26 nurses who had passed through an attack of scarlet fever whilst in this hospital, 23 gave a Dick negative reading, and 3 (11 5 per cent) gave a positive reading

Active Immunisation

Dick and Dick[2] have found that it is possible to render the Dick reaction negative, in a susceptible individual, by the injection of suitable amounts of the specific toxin When the dose is excessive a reaction is produced, consisting of malaise, nausea and vomiting, temperature, and a scarlatinal rash The dose of toxin for immunising purposes is standardised in terms of the skin test dose

The preparation of toxin employed and the method of administration, have already been described We have estimated the immunising dosage in multiples of the skin test dose—*namely, 0 2 c cm of a 1 in 1000 dilution of toxin*

By means of comparative Dick tests applied to nine Dick-positive reactors the toxin content of the immunising preparation (X79, B1811) was found to approximate very closely to that of the test toxin (X48)

A second series of comparative Dick tests performed with a 1 in 1000 dilution of the immunising toxin (X79, B1811), which had been kept in the ice-chest for some nine months in a dilution of 1 in 6, indicated that there had apparently been little or no loss of toxicity on prolonged storage

Immunising Dosage—To arrive at a suitable primary protective injection gradually increasing doses of toxin from 5 to 416 skin test doses were administered to groups of Dick-positive reactors, and any resultant local and systemic symptoms noted Constitutional symptoms began to appear when the initial injection contained 208 skin test doses of toxin Two out of 8 susceptible children, from 1 to 15 years of age, who received the above dose of toxin as a primary injection developed a slight scarlatiniform rash accompanied by a rise of temperature Two subsequent injections of 416 skin test doses of toxin administered 7 and 14 days later to the same group of children produced no systemic disturbance

When a primary injection of 416 skin test doses of toxin was administered to a group of 16 susceptible individuals from 1 to 12 years of age no fewer than 13 developed systemic reactions The close resemblance of the reaction to an attack of scarlet fever was confirmed by the manifest alarm of the experienced ward sister, who, unaware of the nature of the injection, was of the opinion that an explosive outbreak of that disease had developed in her ward It was again noted that the subsequent protective injections of 416 skin test doses of toxin administered 7 and 14 days later were unaccompanied by constitutional disturbance

We finally decided to administer 200 skin test doses of toxin as a primary protective injection to susceptible members of the nursing staff Fifty-one Dick positive nurses received immunising injections To 35 of these, a course of 4 injections at 5-day intervals, of 200, 400, 800 and 1000 skin test doses of toxin was administered More recently, a course of 3 injections, at 14-day intervals, of 200, 1000, and 2000 skin test doses of toxin, has been tried in 7 nurses Nine nurses, for one reason or another, did not complete the full course

Reactions Following Immunising Injections

The local reactions were on the whole trifling In one nurse, a painful indurated area of erythema, 6 cm by 5 cm, was accompanied by an erythematous rash which extended from shoulder to hand

Fourteen nurses complained of more or less systemic disturbance following the primary protective injection Slight headache was noted in five, whilst the remainder complained of headache, nausea, or vomiting, and lassitude. Two of the latter reported slight sore-throat In no case was a rash observed One nurse was excused duty for one day, and three for two days each The symptoms appeared within a few hours of the injection, and lasted from a few hours to, in one case, three days Systemic reactions were more marked in nurses who gave a brilliant positive Dick reading of 2 5 cm. to 3 cm or more in diameter An initial immunising injection of only 100 skin test doses of toxin, administered to a nurse whose Dick reaction measured 5 cm by 3 5 cm., was followed by headache and nausea the same evening A second injection of 200 skin test doses of toxin, five days later, resulted in headache and vomiting within some eight hours of the protective inoculation There was a slight pseudo in this case 1 cm by 0 7 cm in diameter

[2] Dick G F, and Dick, G H Jour. Amer Med Assoc, July 12th, 1924

Development of Immunity

Of 35 nurses who received the full course of four injections of approximately 200, 400, 800, and 1000 skin test doses of toxin, at five-day intervals, 33 were retested Twenty (60 6 per cent) were found to be Dick negative within 6 weeks of completion of the immunising course, whilst 13 still showed susceptibility, markedly diminished in the majority.

Of seven nurses who received the course of three injections, at 14-day intervals, of 200, 1000, and 2000 skin test doses of toxin, three became Dick negative with 2 weeks, 4 within 4 weeks, and 5 (71 4 per cent) within six weeks of the administration of the last protective injection.

The administration of a second immunising course of from 1500 to 3000 skin test doses of toxin, to 13 remaining Dick positive reactors, resulted in seven becoming Dick negative within a period of four to 8 months from the completion of the primary immunising course Three were still Dick positive at four, five, and eight months, whilst the remaining three left hospital

Of the nine nurses who did not receive the full course of protective injections, five became Dick negative within two to five months of inoculation, one developed scarlet fever, which resulted in a negative Dick test in the fourth week of disease; two were still susceptible prior to leaving hospital six months later, and one has yet the course to complete

Summarising these results we find that of 42 originally Dick positive nurses, 37 (88 1 per cent) were rendered Dick negative by injections of the specific toxin, within varying periods of time up to eight months from the completion of the primary course of protective injections

Duration of Immunity.

A retest was recently applied to a group of nine nurses, who 11 months ago were found to have developed immunity subsequent to a course of protective injections Four still gave a negative Dick reading The remaining five were again Dick positive In a second group of five girls who became Dick negative subsequent to active immunisation, a retest applied eight months later revealed that two had lost their acquired immunity within that time

It was noted that those nurses in whom the period of immunity had lasted less than 8 and 11 months respectively, had shown at the original test a high degree of susceptibility to scarlet fever, as evidenced by large and brilliant Dick reactions Where the original Dick test indicated a slight susceptibility to the disease, not only was immunisation more rapidly attained, but in the few retested was still present 8 and 11 months later

Incidence of Scarlet Fever in the Nursing Staff

I regret to state that since this work was initiated some 18 months ago, two nurses, noted as Dick negative with the Edinburgh preparation of toxin, developed scarlet fever six weeks and six months respectively, after the application of the test

In one case the test, read at 8, 24, and 48 hours, gave so indefinite a reaction that we were unable to measure the area involved, and hence was noted as query negative This nurse developed undoubted clinical scarlet fever of moderate severity six weeks later A positive Schultz-Charlton was obtained with a 1 in 100 dilution of scarlet antitoxin The injection of 0 2 c cm of the patient's blood serum, obtained on the twenty-fourth day of disease, into a first day scarlet rash, produced an area of blanching 2 5 by 3 1 cm in diameter It is interesting to note that a Dick test applied on the third day of disease with the London preparation of toxin (X48), gave a frank negative reading

Another nurse, 18 years of age, who had not suffered from scarlet fever previously, when tested on Jan 11th, 1926, showed at the 8-hour reading an area of faint erythema 1 0 cm by 1 2 cm on both test and control arms At the 24 and 48 hour readings there was no reaction visible on either arm The case was noted as Dick negative On June 5th, 1926, this girl developed a mild attack of scarlet fever

Six cases of scarlet fever have occurred in Dick positive nurses In two the disease developed before the application of the test, but a positive result was obtained on the third day of disease in both cases. One nurse developed scarlet fever the day following the application of the test, and thus frustrated our recommendation that, on account of her brilliant Dick reaction, she should be excluded from duty in the scarlet fever pavilions until successfully immunised Three nurses contracted the malady 11, 27, and 60 days respectively after completing the immunising course

Annual Incidence of Scarlet Fever in the Staff

During the year 1926 five nurses contracted scarlet fever One case developed in a Dick negative reactor, whilst the other four occurred in Dick positive nurses Particulars of these four cases have already been noted above No nurse who was successfully immunised has yet contracted the disease.

In Table III is shown the annual incidence of scarlet fever in the nursing staff during the past seven years

TABLE III —*Annual Incidence of Scarlatina in Nursing Staff.*

Year	Total staff	Number of cases of scarlatina in staff	Incidence per cent	Total number of scarlatina cases admitted
1920	148	14	9 46	1382
1921	146	15	10 27	1983
1922	147	9	6 12	1559
1923	137	6	4 38	1741
1924	128	11	8 59	1604
1925	161	15	9 31	1906
1926	142	5	3 52	1612

Owing to the wide fluctuation in the annual incidence of scarlatina among the staff, it is not possible to arrive at a definite conclusion, yet it is at least encouraging, that the lowest incidence yet encountered should coincide with the application of specific measures of prevention

Conclusions

1 By the injection, at intervals of from 5 to 14 days, of gradually increasing doses of scarlet fever toxin, it is possible to render the majority of Dick positive reactors Dick negative.

2 Providing the dosage is carefully graded this can be accomplished without the development of any unpleasant or permanent ill-effects

3 Whilst active immunity can be attained by the injection of relatively small doses of toxin, its duration in cases originally strongly Dick positive is only a matter of months

4 Should a more lasting immunity be desired in marked Dick positive reactors, much larger injections of toxin than we have employed are apparently necessary.

TESTICULAR GRAFTING

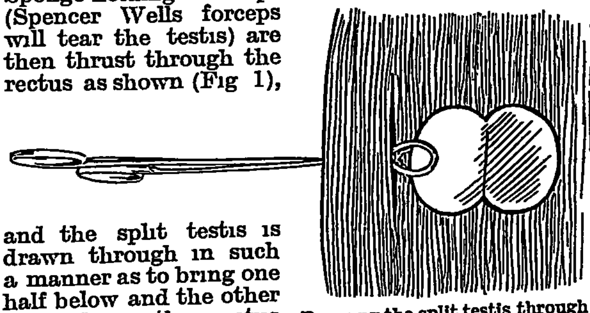
By HAMILTON BAILEY, F R C S Eng,
GILLSON SCHOLAR, SOCIETY OF APOTHECARIES, SURGEON DUDLEY ROAD HOSPITAL, BIRMINGHAM

There is no doubt that the internal secretion of the testis has a very profound effect upon the vitality of the organism The work of Voronoff has abundantly proved, in both men and animals, that the testicular hormone may be, at least temporarily, supplemented by a graft, which, in the case of man, is made from the anthropoid apes

Voronoff's operation is to implant slices of the testis into the scarified tunica vaginalis, but this can only be done in those cases in which the tunica is distended by (even a small quantity of) hydrocele fluid He states that the ideal site for the graft is within the tunica, for in this situation it is to a large extent nourished by the plasma (hydrocele fluid) which bathes it Nevertheless, from a detailed study of his cases, we glean that the intravaginal implantation is, for anatomical reasons, rarely possible Thus, of 43 cases in which operative details are given,[1] the site of the grafts was as follows (1) outside the tunica vaginalis, 30, (2) partly outside and partly inside, 12; (3) entirely inside, 1 From these figures it can be gathered that as all the groups were equally successful the secretion of the tunica can have but little effect upon the nutrition of the graft If this is so, there is nothing to recommend particularly the cellular tissues of the scrotum as the ideal site for a graft

I have grafted the testis into the sheath of the rectus abdominis on five occasions by the following technique The epididymis is cut away with scissors, and the testis split longitudinally The rectus sheath is opened, and the medial border of the rectus muscle mobilised. Sponge-holding forceps (Spencer Wells forceps will tear the testis) are then thrust through the rectus as shown (Fig 1), and the split testis is drawn through in such a manner as to bring one half below and the other half above the rectus muscle The edges of the cut surfaces are then sutured together (Fig 2) The rectus muscle offers a uniformly satisfactory site for the implanted organ, as it is exceedingly well supplied with blood by the deep epigastric vessels

Fig 1.



Drawing the split testis through the rectus muscle

In four of these cases orchidectomy had to be performed for maldescent of the testis In all cases orchidopexy was impracticable because of the shortness of the vas deferens The extirpated testis was placed in saline solution at body temperature until the inguinal wound had been sewn up The testis was then grafted into the rectus sheath of its owner

The fifth case is of sufficient interest to give some detailed notes —

J P, aged 65, was admitted to hospital on Jan 10th, 1926, with a periurethral abscess and commencing extravasation of urine For ten days he had had almost complete retention The temperature was 102° F, and he was profoundly uræmic Under intrathecal stovaine anæsthesia external urethrotomy was performed, and a catheter passed from the perineum into the bladder The infiltrated scrotum was also incised By the beginning of February, after a stormy convalescence, he had sufficiently recovered for us to contemplate the treatment of the stricture At this time it was observed that he looked very old for his years, and that his mentality was sluggish On Feb 4th it was arranged to treat the stricture by internal urethrotomy On the same day it was necessary to remove a maldescended testis from a healthy young man in whom orchidopexy had been, a year previously, attempted unsuccessfully The excised testis, which was well formed, was transplanted into the rectus sheath of the old man.

I have had this man under weekly observation for a year For six months the grafted organ could be felt in the abdominal wall undiminished in size During the seventh month it rapidly decreased, and, at the present time (January) although palpable, it is only a quarter of its original dimensions After making an allowance for an improved renal function, I am convinced that some degree of rejuvenation took place The patient's movements became quicker, his expression more alert, he volunteered the information that his neighbours remarked upon his energy, and he was able to return to work after an enforced idleness of nearly three years During the past two months I have detected some regression, but the patient remains in good health

Fig 2

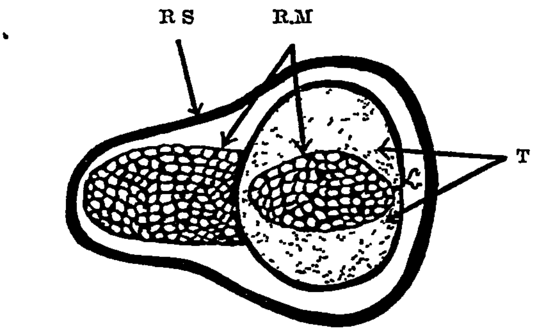


Diagram to show the relationship of the grafted testis to the rectus muscle The operation completed
R S = Rectus sheath R M = Rectus muscle T = Testis

The problem of scientifically estimating the effects of any type of rejuvenation is an exceedingly difficult one, and is not solved by the camera After performing some 25 Steinach ligations in the course of such operations as prostatectomy and herniotomy in elderly men, I am uncertain of its result On the other hand, testicular grafting appears to be a method full of promise, nevertheless, the restorative effect is probably quite temporary In a country where anthropoids are scarce and antivivisectionists abound, the utilisation of extirpated maldescended testes, which otherwise could be thrown away, offers an economical, though limited, avenue by which we may add to our knowledge

Erratum —Early copies of our last week's issue contained an obvious error In the first column of Tables I, II, and III of Prof H B Dixon's special article on the Ignition Points of Gases in Nitrous Oxide (pp 247, 248) the "lag" interval between the issue of the gas and its ignition should have been noted in seconds, so that the abbreviation following the figures should have been *secs* instead of *m*

Spa Practitioners' Association —A meeting held in London on Jan 21st was attended by 20 medical men from various British spas Dr Kerr Pringle (Harrogate) took the chair, and on the motion of Dr C W Buckley (Buxton), seconded by Dr R Ackerley (Llandrindod Wells), it was decided to form a society to be called the Spa Practitioners' Association, which should represent the interests of those engaged in spa practice Membership is to be open to all registered medical men and women practising at a British spa, the annual fee for membership being 10*s* 6*d* The following officers of the Association were appointed President, Dr Kerr Pringle (Harrogate), Secretary, Dr J B Burt (Buxton), Members of Council, Dr Vincent Coates (Bath), Dr F Clayton (Leamington), Dr R Ackerley (Llandrindod Wells), and Dr Leonard Boys (Woodhall)

Medical Societies.

TUBERCULOSIS SOCIETY

AT a meeting of this Society, held on Jan 14th, Dr JAMES WATT, the President, in the chair, Dr. C D S AGASSIZ read a paper on the

Differential Diagnosis of Non-Tuberculous Fibrosis of the Lungs

His experience of this condition, he said, was confined to cases in children, and he wished to draw attention to some points in the differential diagnosis which were not sufficiently stressed The incidence appeared to be greatest in children of from 5 to 10 years of age There was no evidence of a familial tendency. A history of an antecedent attack of broncho-pneumonia or whooping-cough was commonly met with The most constant symptom was cough, which recurred especially in the winter and was accompanied by little or no sputum. When sputum was present it was tenacious and mucopurulent There might be a good deal of dyspnœa, which, however, appeared to cause comparatively little distress Hæmoptysis was rare, but cyanosis was frequently present and was of some importance Clubbing of fingers occurred in about two-thirds of the cases. The physical signs varied with the extent of the disease The cardiac impulse was displaced; vocal fremitus might be diminished but was always present Auscultation showed the breath sounds to be diminished, dry, leathery, creaking râles were usually present but were very inconstant The temperature charts might either show a slight pyrexia of at most 101° or 102° F, which would fall in a day or two and would not be accompanied by increased respiration, or they might show a temperature rising sharply to 102° or more, remaining elevated for a week or so, and being accompanied by a respiratory rate of 30, 40, or 50 In 90 per cent of these cases the Pirquet reaction was negative, while it was a curious fact that in 10 per cent the Wassermann reaction was positive Radiography was of great importance in cases of non-tuberculous fibrosis The cardiac shadow was often displaced Shadows were to be seen at the root of the lung and radiating from it, varying from slight streaks to dense striations The diaphragmatic shadow was irregular, and "peaking" would often be found on the inner two-thirds of the diaphragm, being probably due to adhesions The root-shadows and basal shadows might be more marked in one lung, but were usually seen in both

The subjects of non-tuberculous pulmonary fibrosis, seemed, said Dr Agassiz, liable particularly to secondary infections—e g, otorrhœa, tonsillitis, and skin diseases such as impetigo In pulmonary tuberculosis there was in about 80 per cent of cases a history of contact with tuberculous *infection* The history also frequently recorded influenza or hæmoptysis, whilst often the disease was only discovered during a routine examination at school The sputum was more profuse than in pulmonary fibrosis Hæmoptysis was frequent, but cyanosis was comparatively rare unless fibrosis was also present Clubbing was usually absent or inconspicuous The percussion note was impaired chiefly over the apex, adventitious sounds also were usually present there, and were more constant than in non-tuberculous fibrosis Respiration might be normal, but the pulse-rate was usually increased Radiography generally showed a woolly mottling at the apex or radiating down from it The diaphragmatic outline was less irregular than in fibrosis Septic complications were not common, and when present they were of the type usually associated with pulmonary tuberculosis—e g, pleurisy

The question arose, continued Dr Agassiz, whether these two pictures might not represent different stages of tuberculosis Personally he was no believer in the so-called hilum tuberculosis Many cases began in infancy He had under his care at that time six infants who showed all the signs he had enumerated as typical of fibrosis The root shadows were only slightly increased. There was a definite contrast between the physical signs and the X ray picture in the two conditions, and another important distinction was the high percentage of negative Pirquet reactions in cases of fibrosis It had sometimes been suggested that the tubercle bacillus might start the process and then die out or give rise to a peribronchial tuberculosis He thought this sequence might occasionally take place, but probably not often, and it was difficult to see why the fibrosis should increase The presence of cyanosis was also suggestive of fibrosis rather than of peribronchial tuberculosis It had been shown that one-third of the lung area must be involved to produce cyanosis, and it was impossible to believe that one-third of the alveoli could be affected and yet give rise to no increase of root shadows The after-history of the cases was also important In a series of 50 cases of fibrosis, no less than 48 were still alive after three to four years, and all of these were at work Lastly, there was the question of post-mortem evidence, which was suggestive, though not yet conclusive He had had one or two post-mortem examinations on cases which had died of fibrosis, and sections examined microscopically showed no signs of tuberculosis

Other diseases, said Dr Agassiz, in conclusion, might also sometimes cause difficulty in diagnosis Chronic bronchitis was uncommon in children, the chest tended to become emphysematous, and the percussion note hyperresonant There was no displacement of the heart Pleural effusion could be diagnosed by the exploring needle. Thickened pleura might present some difficulty, but in any case the condition was probably always present to some extent in fibrosis of the lung In broncho-pneumonia diagnosis might not be possible during the height of an attack

Discussion

The PRESIDENT said that he found it difficult to get over the fact of a negative Pirquet in so many cases If Dr Agassiz were right, it meant that about one-third of the children that were being sent to sanatoriums were being sent unnecessarily What happened to these children afterwards? They ought to turn into typical cases of bronchiectasis, but he doubted whether they did so, and whether there were enough cases of bronchiectasis to go round

Dr G. T HEBERT said that he had followed up some of these cases of fibrosis for 10 or 12 years He had often been struck with the physical well-being of the children who had extensive physical signs He agreed with Dr Agassiz that most of the cases were non-tuberculous, although the point could not be definitely settled till after the cases had been followed for a longer period At one time he had come across two or three cases of pulmonary fibrosis associated with enlarged cervical glands, and would like to know whether this was a common association The presence of moist sounds in the chest was difficult to account for in the comparative absence of sputum; possibly it was due to a certain amount of œdema He agreed strongly with the statement as to the importance of radiography in these cases Fibrous tissue, he thought, did not show up on X ray pictures as much as radiologists believed, lack of opacity was striking in these cases of non-tuberculous basal fibrosis He looked upon these cases as the main source of bronchiectasis in adults, but the course taken by the disease naturally depended on the resistance in any given case

Dr MACDONALD concurred with Dr Hebert's views as to the X ray appearance in cases of fibrosis, instancing a case of his own in which physical signs were found on the side which was most translucent on the screen

Dr G B PRICE said that he was not clear whether the fibrosis mentioned by Dr Agassiz was localised or general Vascular conditions almost certainly gave rise to fibrosis He himself labelled cases as tuberculous with reluctance, but he had followed up a

TESTICULAR GRAFTING

By HAMILTON BAILEY, F R C S Eng ,
GILLSON SCHOLAR, SOCIETY OF APOTHECARIES, SURGEON DUDLEY ROAD HOSPITAL, BIRMINGHAM

There is no doubt that the internal secretion of the testis has a very profound effect upon the vitality of the organism The work of Voronoff has abundantly proved, in both men and animals, that the testicular hormone may be, at least temporarily, supplemented by a graft, which, in the case of man, is made from the anthropoid apes

Voronoff's operation is to implant slices of the testis into the scarified tunica vaginalis, but this can only be done in those cases in which the tunica is distended by (even a small quantity of) hydrocele fluid He states that the ideal site for the graft is within the tunica, for in this situation it is to a large extent nourished by the plasma (hydrocele fluid) which bathes it Nevertheless, from a detailed study of his cases, we glean that the intravaginal implantation is, for anatomical reasons, rarely possible Thus, of 43 cases in which operative details are given,[1] the site of the grafts was as follows . (1) outside the tunica vaginalis, 30 ; (2) partly outside and partly inside, 12 ; (3) entirely inside, 1 From these figures it can be gathered that as all the groups were equally successful the secretion of the tunica can have but little effect upon the nutrition of the graft If this is so, there is nothing to recommend particularly the cellular tissues of the scrotum as the ideal site for a graft

I have grafted the testis into the sheath of the rectus abdominis on five occasions by the following technique The epididymis is cut away with scissors, and the testis split longitudinally The rectus sheath is opened, and the medial border of the rectus muscle mobilised Sponge-holding forceps (Spencer Wells forceps will tear the testis) are then thrust through the rectus as shown (Fig 1), and the split testis is drawn through in such a manner as to bring one half below and the other half above the rectus muscle The edges of the cut surfaces are then sutured together (Fig 2) The rectus muscle offers a uniformly satisfactory site for the implanted organ, as it is exceedingly well supplied with blood by the deep epigastric vessels

Fig 1.

TUBERCULOSIS SOCIETY.

At a meeting of this Society, held on Jan. 14th, Dr. **James Watt**, the President in the chair, Dr C D S **Agassiz** read a paper on the

Differential Diagnosis of Non-Tuberculous Fibrosis of the Lungs.

His experience of this condition, he said, was confined to cases in children, and he wished to draw attention to some points in the differential diagnosis which were not sufficiently stressed The incidence appeared to be greatest in children of from 5 to 10 years of age There was no evidence of a familial tendency A history of an antecedent attack of broncho-pneumonia or whooping-cough was commonly met with The most constant symptom was cough, which recurred especially in the winter and was accompanied by little or no sputum. When sputum was present it was tenacious and mucopurulent There might be a good deal of dyspnœa, which, however, appeared to cause comparatively little distress Hæmoptysis was rare, but cyanosis was frequently present and was of some importance. Clubbing of fingers occurred in about two-thirds of the cases The physical signs varied with the extent of the disease The cardiac impulse was displaced; vocal fremitus might be diminished but was always present Auscultation showed the breath sounds to be diminished; dry, leathery, creaking râles were usually present but were very inconstant The temperature charts might either show a slight pyrexia of at most 101° or 102° F, which would fall in a day or two and would not be accompanied by increased respiration, or they might show a temperature rising sharply to 102° or more, remaining elevated for a week or so, and being accompanied by a respiratory rate of 30, 40, or 50 In 90 per cent of these cases the Pirquet reaction was negative, while it was a curious fact that in 10 per cent the Wassermann reaction was positive Radiography was of great importance in cases of non-tuberculous fibrosis The cardiac shadow was often displaced Shadows were to be seen at the root of the lung and radiating from it, varying from slight streaks to dense striations The diaphragmatic shadow was irregular, and "peaking" would often be found on the inner two-thirds of the diaphragm, being probably due to adhesions The root-shadows and basal shadows might be more marked in one lung, but were usually seen in both

The subjects of non-tuberculous pulmonary fibrosis, seemed, said Dr Agassiz, liable particularly to secondary infections—e g, otorrhœa, tonsillitis, and skin diseases such as impetigo In pulmonary tuberculosis there was in about 80 per cent of cases a history of contact with tuberculous infection The history also frequently recorded influenza or hæmoptysis; whilst often the disease was only discovered during a routine examination at school The sputum was more profuse than in pulmonary fibrosis Hæmoptysis was frequent, but cyanosis was comparatively rare unless fibrosis was also present Clubbing was usually absent or inconspicuous The percussion note was impaired chiefly over the apex, adventitious sounds also were usually present there, and were more constant than in non-tuberculous fibrosis Respiration might be normal, but the pulse-rate was usually increased Radiography generally showed a woolly mottling at the apex or radiating down from it The diaphragmatic outline was less irregular than in fibrosis Septic complications were not common, and when present they were of the type usually associated with pulmonary tuberculosis—e g pleurisy

The question arose, continued Dr Agassiz, whether these two pictures might not represent different stages of tuberculosis Personally he was no believer in the so-called hilum tuberculosis Many cases began in infancy. He had under his care at that time six infants who showed all the signs he had enumerated as typical of fibrosis The root shadows were only slightly increased. There was a definite contrast between the physical signs and the X ray picture in the two conditions, and another important distinction was the high percentage of negative Pirquet reactions in cases of fibrosis It had sometimes been suggested that the tubercle bacillus might start the process and then die out or give rise to a peribronchial tuberculosis. He thought this sequence might occasionally take place, but probably not often, and it was difficult to see why the fibrosis should increase The presence of cyanosis was also suggestive of fibrosis rather than of peribronchial tuberculosis It had been shown that one-third of the lung area must be involved to produce cyanosis, and it was impossible to believe that one-third of the alveoli could be affected and yet give rise to no increase of root shadows The after-history of the cases was also important. In a series of 50 cases of fibrosis, no less than 48 were still alive after three to four years, and all of these were at work. Lastly, there was the question of post-mortem evidence, which was suggestive, though not yet conclusive He had had one or two post-mortem examinations on cases which had died of fibrosis, and sections examined microscopically showed no signs of tuberculosis

Other diseases, said Dr. Agassiz in conclusion, might also sometimes cause difficulty in diagnosis Chronic bronchitis was uncommon in children; the chest tended to become emphysematous, and the percussion note hyperresonant There was no displacement of the heart Pleural effusion could be diagnosed by the exploring needle. Thickened pleura might present some difficulty, but in any case the condition was probably always present to some extent in fibrosis of the lung. In broncho-pneumonia diagnosis might not be possible during the height of an attack

Discussion.

The **President** said that he found it difficult to get over the fact of a negative Pirquet in so many cases. If Dr Agassiz were right, it meant that about one-third of the children that were being sent to sanatoriums were being sent unnecessarily. What happened to these children afterwards? They ought to turn into typical cases of bronchiectasis but he doubted whether they did so and whether there were enough cases of bronchiectasis to go round.

Dr G T. **Hebert** said that he had followed up some of these cases of fibrosis for 10 or 12 years. He had often been struck with the physical well-being of the children who had extensive physical signs He agreed with Dr Agassiz that most of the cases were non-tuberculous, although the point could not be definitely settled till after the cases had been followed for a longer period At one time he had come across two or three cases of pulmonary fibrosis associated with enlarged cervical glands, and would like to know whether this was a common association The presence of moist sounds in the chest was difficult to account for in the comparative absence of sputum; possibly it was due to a certain amount of œdema. He agreed strongly with the statement as to the importance of radiography in these cases. Fibrous tissue, he thought, did not show up on X ray pictures as much as radiologists believed; lack of opacity was striking in these cases of non-tuberculous basal fibrosis He looked upon these cases as the main source of bronchiectasis in adults, but the course taken by the disease naturally depended on the resistance in any given case

Dr **Macdonald** concurred with Dr. Hebert's views as to the X ray appearance in cases of fibrosis, instancing a case of his own in which physical signs were found on the side which was most translucent on the screen

Dr G B **Price** said that he was not clear whether the fibrosis mentioned by Dr Agassiz was localised or general. Vascular conditions almost certainly gave rise to fibrosis He himself labelled cases as tuberculous with reluctance, but he had followed up a large number of adult patients who had been diagnosed as fibrotic, and after some years tubercle bacilli had been found in the sputum of a certain number of them

Dr P A GALPIN said that he had come across a great number of cases in which there had been repeated attacks of broncho-pneumonia with a history of cough but a paucity of symptoms and a good general condition Such cases, giving abundant physical signs but few symptoms, were probably non-tuberculous There seemed to be here some analogy with cases of bone disease—tuberculosis contrasted with sclerosis of the bone The tendency to destruction was greater in tuberculosis, while the tendency to sclerosis was greater in pyogenic conditions The final test in both groups must be pathological

Dr C F PEDLEY said that at one time he used to receive cases unlabelled Nearly all these were associated with a nasopharyngeal condition As a school medical officer, he hardly ever diagnosed tuberculosis, a nasopharyngeal catarrh was usually present

Dr T R ELLIOTT agreed with the lecturer that a large number of cases were wrongly diagnosed as tuberculous. In Shropshire he had had cases with enlarged mediastinal glands in which there was definite fibrosis at the root of the lung He wondered whether the fibrosis in such cases was congestive, due to pressure from the enlarged mediastinal glands A history of contact with tuberculosis was an important point in the diagnosis, as was also a peculiar smell of sweat associated with tuberculosis

Dr BRAND thought that the fibroid type of tuberculosis was uncommon in children under 15 years of age, owing to the lack of resistance He believed that bronchiectasis began at a much earlier age than the speakers appeared to think Fibrosis merely represented the reaction of the tissues to a bacterial agent, it was symptomless and signless Every degree could be present up to an extreme fibrosis causing interference with blood-vessels, alveoli, and bronchi He also was a believer in the theory of Dr Agassiz, and had no difficulty in looking upon these cases as non-tuberculous He thought that a child who had pulmonary fibrosis plus bronchiectasis had very little chance of getting through to adult life without being notified several times over as suffering from pulmonary tuberculosis

Dr. F R WALTERS said that the points of difference between the two conditions seemed clear in children, but diagnosis was not so easy in adults

Dr C ROPER said that he had met with a large number of persons suffering from miner's phthisis, and was convinced of the widespread existence of non-tuberculous fibrosis, although it might happen sometimes that tuberculosis was engrafted upon it later on

Reply

Dr AGASSIZ, in reply, spoke of the after-history of the patients A certain number of cases, he believed, went on to bronchiectasis, others in adult life were labelled chronic bronchitis; some would probably clear up altogether Lipiodol might throw a good deal of light upon some of these cases Some probably did develop tuberculosis afterwards He thought that cervical adenitis undoubtedly did occur in association with fibrosis Interlobar pleurisy was probably not as uncommon as was sometimes believed, and it might quite well lead to fibrosis One or two speakers had referred to the comparative rarity of pulmonary tuberculosis in children About one-third of his own cases had tubercle bacilli in the sputum, and more than these had bacilli in the fæces He had had quite a number of patients, aged three, who had had positive sputum Symptoms in fibrosis were undoubtedly less complained of by children He agreed that chronic nasopharyngeal infectious conditions were extremely common and might very possibly cause fibrosis, and he thought that fibrosis was more common in both children and adults than was usually recognised

The PRESIDENT suggested that tuberculosis officers might help in the elucidation of the question by a careful following up of their cases of fibrosis

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY

AT a meeting of this Section held on Jan 20th Dr J H SEQUEIRA, the President, took the chair and Mr. H. S. SOUTTAR demonstrated the

ACTION AND USES OF A STEAM-HEATED CAUTERY

which has been described by him in THE LANCET[1] The use of heat coagulation, he said, in the destruction of malignant growths often had advantages over their removal by direct surgery When properly used there was no hæmorrhage, and it was thus possible to deal with fungating masses where the direct control of hæmorrhage by ordinary surgical methods was impossible Provided the heat was applied at a low enough temperature, any degree of penetration could be obtained, and a dense covering of coagulated tissue was formed which allowed the deeper tissues to granulate under ideal conditions of asepsis These results had usually been obtained by means of diathermy, but it had appeared to him that they could be got more simply and effectively with an applicator maintained at a constant temperature by a current of dry steam His apparatus consisted of a small boiler in which "Meta Fuel" was used as a source of heat The steam was slightly superheated by being carried directly through a flame, and was conveyed by a thick rubber tube to an insulated handle This terminated in a nozzle on to which applicators of various forms and dimensions could be screwed, and the steam, after passing through the applicator returned by the handle to the discharge tube The applicator was thus kept at a constant temperature of approximately 100° C, and so long as it was kept in contact with the tissues heat slowly penetrated and produced coagulation, as the temperature of the applicator was absolutely constant the depth of penetration could be gauged with great accuracy With large applicators, and on moist tissues, penetration occurred at a rate of about one inch in ten minutes With small applicators minute defects such as spider nævi could be destroyed in a few seconds The range of applicability was therefore very large, and the instrument could be used with equal facility for the destruction of huge masses of fungating carcinoma and for the removal of minute cutaneous defects The method had been found of peculiar value in the treatment of epithelioma of the skin arising on a scarred surface, e g, after treatment for lupus and similar conditions by X rays In such cases excision would leave a widely gaping wound which could only be closed with great difficulty With the steam cautery these growths could usually be destroyed quite easily under local anæsthesia, and when the slough separated a granular surface was left which was easily covered by epithelium

Mr. Souttar then described and showed a number of cases, most of which were reported in article already referred to

Dr H SEMON showed three cases treated by the method

1 —Carcinoma on lupus treated by X rays in 1904 The patient, a man aged 65, had suffered from lupus vulgaris of the right side of his face and nose for over 20 years When he was seen at the Royal Northern Hospital in March 1926, there was a moist fungating tumour in the midst of a patch of X ray atrophy on the right cheek The growth had extended deeply into the subcutaneous tissue and through the buccinator muscle Under general anæsthesia the tumour was scraped away, over a palpating finger placed in the patient's mouth This enabled the operator to ascertain that the mucous membrane was still intact The exposed area was then treated with the steam cautery in its full extent, and for a distance of about half an inch beyond its apparent limits The lesion healed completely in three weeks

This case, said Dr Semon, illustrated a notable advantage over diathermy inasmuch as with a finger in the mouth it was very simple to estimate by the increasing heat the exact moment at which the application had to be stopped Such a procedure was not feasible with an electrical coagulation method. The same very practical point was illustrated by the following case :—

---

[1] THE LANCET, 1926, i, 805

2 —A man aged 63. came to hospital on March 10th. 1925, with a septic cauliflower growth on the left ear. The cartilage of the tragus and helix was definitely involved. There was no apparent glandular infection The epithelioma was treated by diathermy, but recurred in September. The second attempt to eradicate it by this method resulted in a perforation of the cartilage. In September 1926, growth had again recurred and on this occasion—after a preliminary excochleation with the sharp spoon, Mr. Souttar's cautery was applied. The result to date is certainly encouraging the only evident relic being the hole left by the second attempt to cure by diathermy, an accident which would have been impossible if the steam cautery had been used in the way suggested in case (1)

3 —A girl of 19 in August of last year asked for the removal of a small hairy mole over the right angle of lower jaw The steam cautery was applied for about 10 seconds to the small stigma.

The result of this treatment, said Dr. Semon. well illustrated a complication whose possibility would have to be taken into account if the instrument was to be used for the treatment of cosmetic defects A keloidal scar such as was fairly common after burns, had developed. and would require treatment with radium. He was of opinion however. that these and other cases confirmed the claims put forward on behalf of this new instrument He thought that it had considerable advantages over diathermy. It was cheap to buy and run could be carried from place to place. and was independent of an electric circuit and did not have the occasional breakdowns to which the diathermy plant was liable Above all it was easy to manipulate and reasonably safe in the hands of any but the most inexperienced.

Dr **ARTHUR WHITFIELD** inquired about the rate of penetration, which, he presumed, diminished with increasing depth from the surface

The **PRESIDENT** said that he was able to support the statements made. from direct experience of the results of the treatment at the London Hospital The results in some cases had been truly remarkable.

Mr. **JOHN EVERIDGE**, Dr. **J. M. H MACLEOD**, and Dr. **M. S. THOMSON** also took part in the discussion.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

AT a recent meeting of this Society, Dr. **JOHN COWAN**, the President, in the chair, Mr **R B CARSLAW** read a paper on

UNDUE MOBILITY AND PROLAPSE OF THE ASCENDING COLON

as a factor in the causation of various abdominal conditions, based on the results of 242 cases treated by colopexy. An early symptom attributable to prolapse of the ascending colon, said Mr Carslaw. was discomfort after food with more or less flatulence, developing later to actual pain which was characteristically variable and inconstant Later there were loss of appetite. increasing flatulence, and frequent bilious attacks, with headache nausea, and malaise. Constipation might or might not be noticed at first, but was invariably present in the later stages. Finally toxic phenomena occurred, such as progressive wasting. pigmentation of the skin chronic mastitis, and, most important of all, mental changes These symptoms were observed in certain groups. which justified classification of the cases into clinical types according to whether they were duodenal. gastric, or referable to the right iliac fossa or elsewhere Referring to the diagnosis of chronic appendicitis, Mr Carslaw said that he considered that there was no such disease. and emphasised the distinction between current attacks of true inflammatory appendicitis and the condition of choked appendix with appendicular colic, unaccompanied by inflammation. Some authors described renal and biliary types associated with attacks of renal and biliary colic, but in his own series these symptoms were additional to the other symptoms. and the patients were not classified in a separate category. Mucous colitis and chronic duodenal ileus were occasional late results

Mr. Carslaw went on to discuss treatment under three headings: (1) preventive: (2) curative by suitable diet, laxatives, and exercises and (3) operative The proper operative procedure. he thought. was to correct the undue mobility and prolapse of the cæcum and ascending colon by Waugh's colopexy. In certain cases fixation of the cæcum was sufficient. but in others not only must the whole ascending colon be fixed. but it was necessary to suspend the right half of the transverse colon as well. Restriction in the undue mobility seemed to be as important as correction of the prolapse or. perhaps, more important still. Any developmental membranes should also be divided. and if there was kinking of the gall-bladder. with stagnation of its contents, it might be necessary to suspend or even drain it after division of its ventral membrane. The appendix, if present should be removed. except in those cases of severe mucous colitis in which appendicostomy was required in addition to colopexy. Where there was marked hepatosis its correction might be helped by shortening the round ligament The right kidney and the uterus should be left alone.

Mr Carslaw summarised as follows the clinical results of 242 consecutive colopexies performed between March. 1920, and July. 1926 :—

Sex and Age Incidence

Age.	Under 9	10–19	20–29	30–39	40–49	50–59	60–69	Total.
Female	1	19	63	57	33	11	1	185
Male	0	9	10	24	9	3	2	57
Total	1	28	73	81	42	14	3	242

Results

Years since operation.	Less than 1	1–2	2–3	3–4	4–5	5–6	6–7	Total.	%
Cured .	10	20	30	31	23	41	13	168	70·3
Very much improved	5	6	13	5	6	5	4	44	18·4
Failures .	0	5	5	5	4	3	5	27	11·3

In the great majority of cases he said, the symptoms disappeared within a few months of operation. The appetite. which had usually been very fickle. rapidly improved, and patients often reported that they were able to eat "anything and everything." The former "bilious attacks" especially in the duodenal type of case, persisted for some months but were much less frequent and very much less severe. Although the characteristic pain. either after food or in the right iliac fossa, soon disappeared, a considerable degree of discomfort was felt in some cases in the right side of the abdomen : this worried the patient for about a year The recovery from constipation—however obstinate it might have been—was one of the most satisfactory results Sometimes a degree of constipation persisted, but as a rule the condition was absolutely cured Another satisfactory result noted in many cases was the disappearance of menstrual irregularities. this occurred too frequently to be mere coincidence There was usually a rapid improvement in general nutrition with steady increase in weight, and the mental outlook was brighter Of the 212 patients who were satisfied with their present condition. 44, although very much improved, were not in his opinion, cured, as they still had some discomfort, occasional flatulence, or some degree of constipation, or had failed to put on weight The remaining 168 were absolutely cured, and that the cure was permanent could be seen from the number of years that had elapsed since operation

Discussion

Mr **ALEXANDER MCLENNAN** said that in 1925 he had performed colopexy by Waugh's method in 20 cases His object in opening the abdomen, however, had been to remove a suspicious appendix. He believed that the appendix ought to be removed on suspicion, and he wholly disagreed with Mr. Carslaw's contention that there was no such thing as chronic appendicitis The benefits which followed from colopexy were sometimes extremely striking It was always difficult to explain the benefit of fixation when the mechanics of the colon were considered It seemed rather absurd to suppose that the ascending colon dragged on the liver, for one of the clinical signs of ascites was that the intestine floated upwards The weight of the ascending colon was a negligible quantity, and he failed to see how it could influence the causation of duodenal ulcer, gall-stones, or any other out-of-the-way disease He could not believe that the ascending colon, by its weight, could drag on any other structures in the abdomen at all. It used to be said that the kidney pushed the ascending colon down but he did not think that the ascending colon ever, pulled the kidney down. Mr Carslaw had mentioned in connexion with Waugh's operation the straightening of the hepatic flexure He (the speaker) suggested that one of the beneficial effects of Waugh's operation was the production of a kink at the hepatic flexure What passed the hepatic flexure then passed it permanently The mechanics of the abdomen and the question of abolishing mobility in the ascending colon were not so simple as they had been led to suppose

Since 1905 at least, said Mr McLennan, he had been in the habit of fixing all cæcums, that he thought were exceedingly mobile He had followed up several of the cases so dealt with, and he thought the procedure resulted in considerable benefit Another benefit was the obliteration of the intercolic membrane Mr Carslaw wanted them to believe that the drop in the ascending colon was the initial process in enteroptosis, but it was an absence of muscular energy which allowed the prolapse If in Waugh's operation a very good pit was made and the ascending colon was put into it, the hepatic flexure came close to the kidney. If the hepatic flexure was pushed from an anterior to a posterior position it was pulled upwards and thus spread out Radiograms ought to be taken from the side to show the colon passing back into the loin Cases of mobile cæcum were being constantly met with In one man of 65, for instance, who had never been ill in his life, the first symptoms of the mobile cæcum were due to volvulus causing sudden intestinal obstruction Tucking-in of the ascending colon allowed the musculature to contract, it made the whole colon shrink and acted as a great support to it In another case presenting symptoms of chronic obstruction, the descending colon, on exploration, looked as if a Waugh's operation had been done on it Mobilisation of the colon cured the condition It must not be forgotten that sometimes striking results were obtained from very slight interference in the abdomen He thought Mr Carslaw incorrect in saying that children had highly placed ascending colons A great deal was said about the ills of humanity being due to the upright position, but he thought the majority of the ills of humanity were due to the want of the upright position

Another Series of Cases

Mr W A **SEWELL** said that colopexy was often denounced most bitterly by those who had little knowledge of the operation If critics would inform operators of their failures, much useful information would be obtained A definite conclusion could only be reached by the analysis of a large number of cases over a considerable period Since 1920 the operation had been performed in the Victoria Infirmary by himself or Mr Macrae in 127 cases Of these patients he had been able to trace only 69, of whom 32 were perfectly well, and 16 much improved In 21 cases the operation had failed, and four of these patients had later died (acute meningitis, tuberculosis, excision of gastric ulcer, and cause unknown) He had deliberately treated two cases by colopexy where the pylorus was under suspicion, but a gastrojejunostomy had been required later and had been followed by marked improvement

Some criticised the operation, said Mr Sewell, on the ground that the symptoms were often due to appendicitis, which was cured by removal of the appendix when colopexy was done Some of the cases were found on admission, or at a later date, to have an appendix normal in size and appearance, but in addition there was a large, loose cæcum which could easily be pulled out of the wound The true diagnosis in these cases was, in his opinion, a volvulus of this loose cæcum Appendicitis was now so well known to the public that the appendix often got credit to which it was not entitled Lichty had reported in 1923 on a series of 400 cases of "chronic appendicitis" Of these, 225 had been cured, in 175, therefore, there had been a mistake in the diagnosis Colopexy was not an alternative to gastrojejunostomy for cases of pyloric ulcer, but was an attempt to prevent the formation of ulcers, and to remove the pull of the loaded ascending colon in that and other regions It was an attempt to cure the symptoms accompanying local and general visceroptosis Colopexy, he thought, undoubtedly lessened and often removed the pain associated with floating kidney, certainly it restricted its movements The results of the operation were by no means perfect, but they were encouraging, and the operation was worthy of further investigation

Criticism of Claims for the Operation

Mr **DONALD DUFF** regarded the claims put forward for the operation as extravagant Common dyspepsia, constipation, gastric ulcers, mesenteric ileus, and even dysmenorrhœa had been put forward as results of a mobile colon, but mobility of the cæcum and ascending colon were normal conditions, and a fixed colon would be the abnormal condition Much had been said about the presence of bands about the lower ileum and cæcum as being of developmental origin, and Lane's ileal kink had been spoken of as one of these. He had had pieces of these bands removed at operation, and had subjected the parts to culture, with the result that *Bacillus coli* had been grown from practically all of them, proving that *the bands were inflammatory in origin and secondary* to constipation A mobile cæcum was frequently seen at abdominal operations, but every case he had seen of such a condition had also a "last kink" well developed If developmental error was the cause of mobile colon, as claimed by Mr Carslaw, it was curious that women should have been selected by nature for the exhibition of this deficiency in the proportion of over 3 to 1, as stated in Mr Carslaw's statistics These figures in fact proved that the enlargement and mobility of the cæcum was secondary to the constipation prevalent in the female sex, it was due not to developmental error but to bad habits He had been able in many instances to cure these cases of obstinate constipation by division of the bands alone without colopexy Colopexy could not be adequately performed without division of Lane's bands, but it was the division of the bands and not the colopexy which produced any good result

Appendicitis and Colopexy

Mr. **ROBERT TENNENT** said that Waugh's operation was attractive because it did not deform nor interfere with the normal physiological action of the bowel, and because it held out prospects of eliminating the dangerous and inefficient methods of colectomy and short circuit Still the claim was so great that he felt a little sceptical He himself had been much impressed by the results of colopexy Nearly all his own cases had been of the right iliac fossa type Hardly a week passed in hospital without an urgent case being admitted labelled "appendicitis," in which the main symptom was pain in the right iliac fossa Some of these patients had been dismissed without operation and later had been readmitted. On operating, it was invariably found that there was a very mobile cæcum, and in these cases simple removal of the appendix would probably be nearly valueless Appendectomy for so-called chronic appendicitis was useless if the cæcum was mobile He had traced about 60 cases where cæcopexy had been performed, and was very pleased with the results With regard to colopexy he could not speak with the same freedon He had rarely done an exploratory operation with the idea of performing colopexy, but he had done colopexy in cases where he had opened the abdomen for some other condition In these cases he was convinced that the operation had been well worth while He had also been struck by the fact that in the few cases of colopexy in males the results had been very unsatisfactory In each of these cases the patient had probably suffered from what Mr McLennan called defective innervation of the colon, for great dilatation was present In such cases there had been no beneficial results whatever. He thought that the relative frequency of the loose colon in women was due to repeated pregnancy With regard to the transverse colon, Waugh's main point was that the ascending colon was the first part of the bowel which had to propel against the force of gravity. The transverse was in a better mechanical position for dealing with the contents than a mobile ascending colon A mobile ascending colon had a lot to do with chronic duodenal ileus, and its correction sometimes had very beneficial results

Experience of the Results

Dr. JOHN RITCHIE, giving details concerning some 30 of his patients on whom Mr Carslaw had operated, said that it was impossible to be apathetic or indifferent when the state of these patients before operation was contrasted with their present condition Some had had pain at a varying period after meals, with flatulence, eructations, gurglings, and splashings Some had had pain a considerable time after meals, with attacks of vomiting One had had such severe pain that a pin-hole perforation of a duodenal ulcer was suspected One had had mucous colitis in addition to other symptoms In some cases the pain had been referred to regions other than the abdomen—e g, the heart, the back, the pelvis, the leg Many suffered from depression, sleeplessness, and obstinate constipation, and some had had previous operations His notes in many cases extended over a considerable period, some of them dating from 1907, and they showed that the patients had been never long off the sick list, turning up with monotonous regularity as semi-invalids He considered the results in practically all his cases to be most satisfactory, relative or absolute health being restored by the operation

Dr WALLACE ANDERSON said that all the cases in his series (operated upon by Mr Carslaw) were drawn from the east end of the city, where conditions were unfavourable to complete and speedy convalescence from any abdominal operation Of 11 cases, he considered that seven were complete "cures," inasmuch as they were now free of symptoms and quite able to carry on their pre-operation duties Of the remaining four, two patients admitted improvement, being able to work, but not being as well as they ought, and hoped, to be Of the other two cases one had a gastrojejunostomy performed some years previously, with no remission of symptoms, and the result of his colopexy was still uncertain The last case had been, he thought, a complete failure She was a typical "abdominal woman" who had had two abdominal operations, presumably gynæcological, without benefit In answer to the criticism that Waugh's operation was effective because it removed a chronically inflamed appendix, he was able to state that in all his cases the appendix had been to all appearance normal His own conclusion, reached after observation of a small number of cases over a number of years, was that colopexy had a definite place in abdominal surgery and deserved careful consideration

Dr W M KNOX said that during the last five years he had had 18 cases treated by colopexy, ten of them had been of long standing and had symptoms of chronic gastro-intestinal intoxication, such as mucous colitis, anæmia, anorexia, constipation, and nervous symptoms All these cases had been treated by dieting, rest for varying periods, and intestinal antiseptics, with only temporary relief. All welcomed operative treatment as a possible escape from their prolonged suffering, and with only two exceptions the results had been satisfactory In three of the other cases the appendix had been previously removed without any amelioration of the condition, but after colopexy recovery was complete The remaining five cases had been of the gastric type of comparatively short duration and were completely cured He therefore welcomed the operation as a satisfactory means of treating a condition which medical treatment had failed to help

Mechanism of Cure

Dr DOUGLAS RUSSELL said that he found difficulty in understanding why, if a mobile cæcum was such a very important factor in the causation of duodenal ulcer, only 10 per cent of these cases were associated with duodenal ulcer There seemed to be a discrepancy Many of the cases were said to be associated with defective innervation, but his opinion was that it was the mentality of the patient that was at fault Dr. Russell showed an X ray film of a patient with a mobile cæcum treated by colopexy four years previously The film showed the cæcum lying in the deepest point of the pelvis, and the stomach atonic and greatly ptosed Yet the patient was undoubtedly cured by operation, although the colopexy had been a complete failure The difficulty was to estimate whether patients of the "mental" type were likely to benefit by operation Such patients could be diagnosed almost at sight by their flabby aspect and stance, due to a wide sigmoidal curve of the vertebral column

Mr JAMES TAYLOR said that it had been suggested that the various bands occurring in connexion with the bowel were congenital in nature and were not acquired as the result of downward traction by the loaded intestine It was perfectly true that there were congenital bands, because the bowel must be supported in some way, even in the child But the bands that Lane had so aptly described as the "crystallisation of lines of force," developed within the congenital folds The one at the termination of the ileum was oftenest seen, not because it was actually the commonest, but because it occurred in the region of the abdomen most often explored by the surgeon It would be seen that this band was a dense white fibrous fascia between the layers of the mesentery, and the under surface of this mesentery had to be cut through to allow of this band being divided. It was a structure that had formed in a congenital fold Mr Taylor suggested that the benefit resulting from colopexy was due to straightening of the terminal ileum This part of the bowel formed a very acute arch, with the cæcum and last inch of the ileum on one side and the next portion of the ileum on the other Lane obtained his result by dividing the band supporting the summit of the arch, whilst Waugh, by fixing the cæcum and ascending colon at a higher level than they were before brought the outer limb of the arch into line with the inner limb As Lane also straightened out the kinked pelvic colon, colopexy was really a modification of part of Lane's operation

Mr JAMES RUSSELL also spoke, and Mr CARSLAW concluded the discussion with a reply.

EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of this Society held on Jan 12th, Prof. R W JOHNSTONE, the President, in the chair, Dr JAMES YOUNG read a paper entitled

Recurrent Pregnancy Toxæmia and its Relation to Placental Damage

In 1914, he said, he had brought before the society evidence suggesting that the eclamptic phenomenon was caused by absorption of toxic elements rapidly elaborated in a mass of dying placenta Since then it had been shown in other connexions that extremely toxic materials, such as histamine and tyramine, might be produced from disintegrating tissue He had at that time described the placental lesion, and, as Strachan had shown recently, his general views had since been confirmed by Clamenz, M'Nalley and Dieckmann, Adair, Soli, and others The assault on the placenta was of such a kind that if it operated over a considerable area of the organ it might cause immediate ending of pregnancy by abortion, premature labour, or accidental hæmorrhage, without toxæmia Where, however, the damage was less marked, it might be consistent with continued life of the fœtus, and, therefore, with the time necessary for the development of the toxic elements responsible for the eclamptic attack Such a view was in harmony with the well-known facts that no essential part of the eclamptic process was direct damage of the fœtus, the life of which might be unharmed even in the most fulminating case, and that, on the other hand, severe eclampsia might suddenly subside after the intra-uterine death of the fœtus and the consequent complete detachment of the placenta

Dr. Young brought forward new evidence derived from a study of 220 successive cases of toxæmia and accidental hæmorrhage in parous women in the Edinburgh Royal Maternity Hospital It was found that in eclamptic cases there was a recurrence of eclampsia or non-convulsive toxæmia in over 30 per cent. This was clearly an underestimate because it did not allow for those cases in which the toxæmia occurring in the last pregnancy, for which the patient was admitted to hospital, was the first of a recurring sequence In addition there was in eclamptic cases a 40 per cent chance of the occurrence in successive pregnancies of abortion, premature labour, accidental hæmorrhage, or stillbirth Examples of this sequence were the following series of pregnancies —

Case A —(1) Premature, (2) and (3) eclampsia
Case B —(1) Abortion, (2) and (3) eclampsia
Case C —(1) and (2) Abortion, (3) eclampsia
Case D —(1) to (7) Normal, (8) *to* (10) abortion, (11) eclampsia

In other words, the morbid process resident in the patient and damaging the successive pregnancies might be primary or acquired In many of the damaged pregnancies of the sequence there was no toxæmia Thus

Case E —(1) and (2) Normal, (3) premature stillbirth with no toxæmia, (4) eclampsia

Case F —(1) Normal, (2) premature, (3) normal, (4) stillbirth with no toxæmia, (5) premature with no toxæmia, (6) eclampsia

Accidental Hæmorrhage

It had long been known, continued Dr Young, that the same absence of toxæmia occurred in many cases of accidental hæmorrhage Toxæmia was present in only about 40 to 50 per cent, and even in patients who died as the result of the hæmorrhage, there might be no evidence of toxic changes in the liver, kidney, or other organs The toxæmia was an accident, and when present was apt to be intense in cases of concealed hæmorrhage—i e, in cases where the damaged placenta was retained within the uterus Dr Young showed that the same abortion, premature birth, toxæmia sequence occurred in this condition Thus -

Case G —(1) Normal, (2) abortion, (3) accidental hæmorrhage

Case H —(1) Normal, (2) accidental hæmorrhage with toxæmia, (3) abortion with no toxæmia, (4) accidental hæmorrhage with no toxæmia

The sequence, said Dr Young, was found in 18 out of 55 cases (32 per cent) He believed that the data indicated that the causes of eclampsia and the related toxæmia of pregnancy were to be found amongst the causes of abortion and premature birth—namely, those which operated by means of placental damage Toxæmia was an accident occurring only in those cases in which, after the placenta was damaged, the abortion or premature birth did not take place quickly enough He stated, further, that the recognition of the high incidence of recurrence in true eclamptic toxæmia and, in eclamptic cases, of the considerable tendency to recurring abortion, premature labour, &c, made necessary a revision of our views regarding so-called nephritic toxæmia It was generally believed that there were two groups of late pregnancy toxæmia, the eclamptic or non-recurrent, and the nephritic or recurrent This distinction was now untenable This statement did not, of course, apply to those comparatively few cases of renal disease clearly acquired before pregnancy—for instance, from scarlet fever—which were sharply marked off from the specific toxæmia in which nephritis was secondary Dr Young believed there was now much evidence for the view that the late pregnancy toxæmias, whether eclamptic or nephritic, had a similar origin in the diseased placenta, and that kidney damage in such cases was secondary and was often aggravated by successive toxic pregnancies This was supported by his own investigations and by those of others, which indicated that chronic nephritis might succeed even one eclamptic attack

Dr DOUGLAS MILLER read a communication on

Occipito-Posterior Position of the Vertex,

based on an analysis of 750 cases of occipito-posterior presentation, mostly seen at the Edinburgh Royal Maternity Hospital In all cases, except for the abnormal position, labour was uncomplicated by contracted pelvis or other major abnormalities, and the series comprised only those cases in which diagnosis of posterior position was made or confirmed during labour They were classified into the following four groups —

Group 1 —*Spontaneous rotation* of the occiput to the front occurred in 474—i e, in rather more than 60 per cent. This figure probably gives too low an estimate of frequency of anterior rotation, as the review necessarily omitted cases admitted late in labour, in which forward rotation of a primarily posterior position may have already taken place Where anterior rotation occurred, the average duration of labour was greater than in primary anterior positions by 2¼ hours in primigravidæ and by 1¾ in multiparæ In 51 cases forceps delivery was ultimately necessary because of fœtal distress or rigidity of the pelvic floor

Group 2 —*Spontaneous delivery with face to pubes* took place in 88 cases, in nine of which the infant was the second of twins In most of the remainder the children were small or the vaginal orifice abnormally lax

Group 3 —In 48 cases (6 4 per cent) the head was seriously delayed at the inlet of the pelvis In approximately two-thirds of these manual rotation of the head was carried out This manœuvre was, as a rule, followed by forceps extraction, although in many cases no further assistance was required Rotation of the head was effected by means of forceps in five cases Internal version was performed in 12 cases and gave much less satisfactory results In the majority of cases, however, this operation was not one of election, but was done as a last resort after labour had become seriously prolonged Craniotomy was performed in two cases in which fœtal death had already occurred

Group 4 —In 140 cases the head was arrested at a low level in the pelvis with the occiput posterior Manual rotation followed by spontaneous or forceps delivery was the treatment adopted in rather more than half of these cases In about 25 per cent rotation was effected by forceps Extraction of the child face to pubes was employed in a small number of cases of severe impaction, whilst craniotomy was performed in eight cases in which delivery of a living child was considered impossible

Discussing these different methods of dealing with the persistent occipito-posterior presentation, Dr Miller said that the results were found to be definitely unfavourable to forceps rotation. In emphasising the importance of diagnosis, he pointed out that in most cases it was possible to decide at an early stage in labour whether forward rotation was likely to occur or not, by careful abdominal and vaginal examination, or by noting such signs as were shown in the following table —

—	*No of cases in which noted*	*(Termination malrotation or non-rotation)*	*Spontaneous forward rotation*
Early rupture of membranes	197	145 (74 %)	52 (26 %)
Delayed engagement of head	139	107 (77 %)	32 (23 %)
Fœtal heart heard both in flank and in opposite anterior lower quadrant	103	78 (76 %)	25 (24 %)
Normal engagement and rupture of membranes at or near full dilatation of os	332	33 (10 %)	299 (90 %)

Dystocia was greatest and morbidity highest, said Dr Miller in the persistent posterior case in which assistance had been delayed until serious impaction had occurred, and he suggested that in the restricted group of cases in which clear indications of faulty flexion were present, rotation of the head and body of the child might with advantage be carried out at or near the commencement of the second stage of labour This proposal of early interference did not run counter to the conservative policy so generally applicable in the management of labour, for against a manœuvre which was comparatively simple and safe when done early, there had to be placed the high probability of difficult intervention after the mother had become exhausted by hours of suffering and fatigue, and fœtal life had sunk to a low ebb.

MANCHESTER MEDICAL SOCIETY AND PATHOLOGICAL SOCIETY

A JOINT meeting of the Manchester Medical Society and the Pathological Society of Manchester was held on Jan 12th, Dr A. A. MUMFORD in the chair

The Dick Test.

Dr D S SUTHERLAND opened a discussion on the Clinical Value of the Dick Test and the Preparation and Use of Scarlet Fever Toxin and Antitoxin He said that in 30 cases of definite scarlet fever during the first three days of the rash distinguishable blanching was obtained in dilutions of immune serum up to 1/5000 in from 12 to 24 hours In two doubtful cases of scarlet fever, where no blanching was obtained, the subsequent clinical symptoms confirmed the diagnosis as being due to a cause other than scarlet fever, and in three cases where the rash was definitely due to another cause no blanching was observed Among the members of the nursing staff at Monsall Hospital, 15 3 per cent were found by the Dick test to be susceptible to scarlet fever, and were immunised before being detailed for duty in scarlet fever wards, 23 per cent were found susceptible to diphtheria and were protected by immunisation During the last six months no cases of scarlet fever or diphtheria had occurred among nurses thus protected Diphtheria patients to the number of 354 were Dick-tested on admission to hospital, of whom 55 9 per cent were found susceptible to scarlet fever the percentage of susceptibles was found highest—83·3 per cent—at the age-period of 1 to 2 years The number of scarlet fever patients Schick-tested on admission for susceptibility to diphtheria was 589, of whom 56 5 per cent were found susceptible The percentage of susceptibles was highest at 5 years of age reaching 75 per cent The standard of immunity of diphtheria patients to scarlet fever was lower than that of patients suffering from scarlet fever to diphtheria, up to the age of 5 years After 7 years the reverse applied, and in both diseases the standard of immunity was much lower than among an average healthy community.

A table of Dick tests with a standard dilution of 1/1000 classified according to day of disease, on 566 definite cases of scarlet fever on admission to hospital, showed, in a survey of 463 patients during the first five days of illness, that 83 6 per cent were Dick positive. Of those giving negative reactions during this period, 36 had intensely marked rashes, which may have masked the reaction On the second day of rash 86 per cent were found to be positive reactors, and, by including possible masked reactions where the rash was intensely marked, this percentage of positive reactors could be raised to 95 5 It was suggested that the remaining 4 5 per cent of negative reactors might be accounted for by rapid development of immunity during the incubation and invasive period of the disease These figures closely approximate to those of Zingher, of New York Dick tests on 150 early cases of scarlet fever, at successive short intervals, demonstrated the establishment of immunity in 90 per cent of cases at from nine to fifteen days, the remaining 10 per cent becoming negative in from two to three weeks In a scrutiny of nearly 800 cases of scarlet fever during the last five months, in about 20 cases where the diagnosis of scarlet fever was undoubted, and where susceptibility, as indicated by the Dick test, had persisted beyond four weeks, a reinfection or relapse had in nearly every case occurred, at periods varying from four to six weeks, followed in a few days by a Dick-negative reaction It was noted that these cases were marked in the primary attack by a very slight degree, or absence, of pyrexia, the other symptoms, including subsequent desquamation, being characteristic It was recommended that such cases be actively immunised, to establish immunity by the twenty-first day. Three hundred skin doses of toxin were sufficient to change a Dick-positive to a Dick-negative reaction, and this dose was unattended by any constitutional disturbance. A Dick test on all cases at the onset of illness and on the twenty-first day was recommended. The use of the test was summarised as follows —

1 A very strongly positive reaction early in the disease and again late in convalescence speaks against the diagnosis of scarlet fever

2 A definite negative reaction during the first two days of rash should put one on guard that he is not dealing with a case of scarlet fever

3 The Dick test should be applied to the diagnosis of sore-throat and pyrexia associated with definite cases of scarlet fever in the same family

4 The test is useful in determining the establishment of active immunisation and in estimating the potency of antitoxic serum

5 In the diagnosis of scarlet fever, the test should be interpreted in relation to the susceptibility of healthy individuals at the age period of the patient.

6 The test is specially useful on the occurrence of scarlet fever in a diphtheria ward The Dick test made, on admission, will indicate without delay the susceptible patients, and protection can be immediately rendered by a prophylactic dose of immune serum. During the last year, on two occasions, in a diphtheria ward of 50 beds, an outbreak of scarlet fever had been followed by no secondary cases when such a course was adopted

7 It is recommended that in surgical wards where exposure to scarlet fever is suspected, patients who have not previously suffered from scarlet fever should be Dick-tested before operation and prophylactic serum administered where the reaction is positive

8 The value of immunisation in case of extensive burns is indicated, even in the absence of exposure to the infection of scarlet fever.

Dr R A. O'BRIEN called attention to the importance of the protection of nursing staffs in fever hospitals and the 10 per cent incidence of scarlet fever in some hospitals At Monsall both diphtheria and scarlet fever were in process of disappearing since Schick and Dick testing and immunisation had been introduced Amongst the nurses, apparently 40 out of 45 with a previous history of scarlet fever gave a negative response to the Dick test, and 18 out of 19 nurses with a previous history of diphtheria gave a negative response to the Schick test The

Dick test during the first three days of the attack of scarlet fever was positive in the Monsall series in 217 out of 251. It was noted, however, that 28 of the negative reactors had very vivid rashes Presumably in such cases the capillaries are dilated to their fullest extent by the circulating toxin, and no local introduction of the Dick test amount of toxin can increase this dilation In other words, these patients present a "universal Dick-positive response." If one deducts these 28 cases, the test was positive in 217 out of 223 patients—i e , 97 per cent The figures for the test applied up to the fifth day of the disease are 388 positive and 27 negative ("vivid rashes" being eliminated)—i e , 93 per cent , whereas from the sixth day onwards the percentage drops to about 60 All such collections of figures show that measurable immunity develops rapidly in the average patient at or about the fifth day This agrees with clinical experience The Schultz-Charlton test was positive in all of 35 successive cases admitted and tested during the first three days of the rash The test is obviously of considerable use in practice, and it is now in routine use in several hospitals in the examination of all "doubtful" cases of scarlet fever Blanching in this series has been got with serum diluted to 1/4000 Evidently a reasonably good serum for clinical use will in this dilution produce blanching in the great majority of patients tested during the first two days of the rash The clinician has thus in his hands a method of rough measurement of the clinical value of any serum he proposes to use for treatment Comparison of the Washington Dick toxin with that in use in many places in this country suggests that in corresponding dilutions the two toxins are of nearly equal potency The comparison will be resumed later when a further sample of the American toxin is available Apparently amongst some 600 to 800 patients convalescent from scarlet fever at Monsall, about 20 gave a positive response to the Dick test at or after the third week of convalescence The Monsall plan was to give a small injection of toxin to patients found to be Dick negative on the twenty-first day and the resultant negative Dick reaction a week later was of great interest to the immunologist and probably of equal interest to the administrator It might prove to be a better way than giving passive immunity to such patients with antitoxin "Second attacks" of scarlet fever during the stay in hospital cause a considerable amount of trouble to all concerned

Dr O'Brien showed figures illustrating the results got by the Parish-Okell rabbit test,[1] which he said promises to be of considerable use in the titration of antitoxin and possibly, conversely, of identification of pathological hæmolytic streptococci

---

[1] THE LANCET, Jan 8th, 1927, p 71

ROYAL MEDICAL BENEVOLENT FUND —At the last meeting of the Committee 44 cases were considered and £769 13*s* 6*d* voted to 40 applicants The following is a summary of some of the cases relieved —

Widow, aged 36, of M B who died suddenly in November last Left with one child aged 2 entirely unprovided for She has recently had a major operation and will not be fit for work for six months Late husband had to help to support his mother and sister which prevented his leaving adequate provision for his wife and child An emergency grant of £10 sent and a further sum of £26 in four instalments was voted

L R F P & S Glasg , aged 84 Four children Wife, aged 80, is paralysed and helpless Only income £12 from investments old age pension £52, and allowance of £90 per annum from second son who also pays for the maintenance of his elder brother who is in a mental hospital Eldest daughter, aged 51, is at home and looks after her parents while the youngest earns 25*s* a week in a warehouse Rent and rates amount to £36 per annum Emergency grant of £10 made and a further sum of £40 in 12 instalments voted

Daughter, aged 52, of M D who practised in the North and died 1874 She lost money on a boarding-house which had to be given up at the end of nine months Teaches music but from lack of pupils asks the Fund for assistance She is lame Total received from teaching in the last 12 months was £88, and £11 from the rent of a house in Scotland Rent and gas 12*s* 6*d* a week Voted £18 in 12 instalments

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W 1

Reviews and Notices of Books.

JACOBI'S ATLAS OF DERMACHROMES

Fourth edition With a new and original text by HENRY MACCORMAC, C B E , M D London William Heinemann, Ltd 1926 With 322 coloured illustrations and two half-tone figures Two vols £5 5*s*

THE first English edition of this well-known German Atlas appeared in 1903, with an English adaptation of the text by the late Dr J. J Pringle. A second edition, containing 159 coloured and 13 black-and-white plates, followed in 1906, and at the urgent request of Prof Jacobi's colleagues was made more complete by a supplement which contained 76 additional coloured plates A German edition, published by Jacobi in 1913, and dedicated to his former teacher the late Prof Neisser, contains 266 coloured and two half tone plates, while the fourth English edition now under review retains all the original plates, and has increased their number to 322 It has also undergone a revision in respect of grouping and general arrangement, and is now a perfect work of its kind The colour standards and the method of printing remain unaltered, it is difficult to see how there could be a better reproduction of flesh tints until photography in natural colour from the living subject is simplified, and made practicable in the clinic

The value of such a collection of plates is comparable to that of a series of specimens in a museum of pathology The dermatologist can use it for teaching purposes or for comparing his own cases with those of colleagues—distant in space or time The practitioner will prize it as an aid to memory, and the fortunate student who has access to such an atlas is enabled to study details which a hurried examination in the out-patient department does not often permit

This is not to suggest that this or any atlas can take the place of careful and repeated study of the actual lesion on the living subject, but that it is a most admirable adjunct thereto A new and entirely original contribution to this edition is the explanatory text by Dr Henry MacCormac This is more detailed than is usual in a work of the kind, and almost reaches the dignity of a text-book of dermatology The descriptions are concise and very clear, all theoretical discussion being avoided The sections on diagnosis and treatment (particularly that of syphilis) are equally satisfying, and if the reader can master and memorise all that is here written, he will have obtained sufficient knowledge to cope with most of the skin cases likely to engage his attention in private practice By the new method of grouping employed, the differences between pemphigus and dermatitis herpetiformis, small-pox and varicella, the various drug eruptions, and other rashes which superficially resemble each other are readily appreciated, and may save the practitioner from potential errors of diagnosis A few gaps in the illustrations might profitably be filled in subsequent reprints or editions There are no pictures, for instance, of the sarcoids, although they are dealt with in the text, while illustrations of acute eczema, furunculosis, and carbuncle might also find a place An alphabetical list of plates accompanies each volume and retains the old and partly discarded classical names used at the time of Hebra and Kaposi The obvious criticism that arises is stifled by the addition of an excellent English index to be found at the end of the second volume. The arrangement and nomenclature are thus rendered comprehensible to any reader, and the work gains an international character.

The book as a whole is a credit to British dermatology, on which both the annotator and the publishers deserve congratulations

DISEASES OF THE SKIN

Fourth edition By JAMES H SEQUEIRA, M D , F R C P Lond , F.R C S Eng , Physician to the Skin Department and Lecturer on Dermatology at the London Hospital London . J. and A Churchill 1927 Pp 644 £2 2s

Dr Sequeira and his publishers are much to be congratulated on this, the latest edition of one of the best known text-books on dermatology Without the least increase in bulk the work has been completely modernised, and contains in readable form all that can be regarded as proven in an expanding and increasingly complex branch of medicine The number and excellence of the illustrations, all of them from typical examples of skin diseases—and many of them in their natural colours—will appeal to the novice, and will not be disdained by the more experienced practitioner The text has undergone no radical alteration, and maintains the concise and lucid style of previous editions In the table of contents there is an improvement in the printing of the various headings, and an increase in their number from 26 to 27, brought about by the introduction of a chapter on disease caused by filterable and other viruses

Dr. Sequeira's clinical experience, probably unrivalled in this country, enables him to give authoritative statistical information based on his own figures The section on the sarcoids, our knowledge of which has been considerably augmented since the last edition was published, contains a good summary and three excellent illustrations from one of the most interesting types of the disease Similar improvements are to be noted in the chapters on ringworm, the erythrodermias and lupus erythematosus The chapter on syphilis may be regarded as the latest word on this vast subject Dr Paul Fildes's contribution on the Wassermann reaction has been extended to include a short account of the "Sigma" test On the subject of light therapy, which Dr Sequeira was one of the first to sponsor in this country, he is regrettably brief His readers would have welcomed from his pen a more detailed exposition of general technique and dermatological indications Apart from this lost opportunity to steady the claims of some of our more enthusiastic radiotherapists, it is difficult to detect a weak spot in this absorbing and conscientious compilation

---

HYDROGEN ION CONCENTRATION

Hydrogen Ion Concentration Its Significance in the Biological Sciences and Methods for its Determinations By LEONOR MICHAELIS, M D , Professor in the University of Berlin, Resident Lecturer in Research Medicine in the Johns Hopkins University Vol. - I Principles of the Theory Authorised translation from the second revised and enlarged German edition, by WILLIAM A PERLZWEIG, M A., Ph D , Associate in Medicine and Chemist to the Medical Clinic in the Johns Hopkins University and Hospital London Baillière, Tindall and Cox 1926 Pp 299 22s 6d

Les Ions d'Hydrogène By W KOPACZEWSKI Paris Gauthier-Villars et Cie 1926 Pp 322 Fr 70

Hydrogen Ion Concentration of the Blood in Health and Disease By J HAROLD AUSTIN, Professor of Research Medicine, University of Pennsylvania; and GLENN E CULLEN, Professor of Biochemistry, Vanderbilt University Medical School London Baillière, Tindall and Cox 1926 Pp 75 9s

THE question of hydrogen-ion concentration and its determination has invaded the province of practically every biological and medical science Starting at first with the researches of Sorensen, it soon became of paramount importance in physical chemistry, was then applied to the study of enzymes, and its subsequent invasion of the field of colloid chemistry made an understanding of the new principle fundamental to the study of biological science

The first monograph to appear on this subject was Prof Michaelis's "Wasserstoff-Ionen-Konzentration" This was published in Berlin in 1914 as a single volume, and contained a brief account of the biological application of the subject, together with some practical methods for the determination of hydrogen-ion concentration and for many years this formed the only available source of information The fact that the work was written in German precluded many workers from taking advantage of the information it contained, and many people who were unacquainted with the language studied German specially to enable them to read the book Every statement in the volume was correct, and every experiment when repeated turned out exactly as described. The second German edition of this work was published some years ago, when, though the literature in the subject had already grown to considerable proportions, it was most welcome, and the English translation of this edition now published will be a great help to workers in this field, for in a subject itself difficult to understand the handicap of attempting to grasp it in a foreign language is considerable The English version is more than a mere translation, too, since it has the full sanction of Prof Michaelis, who has himself added to the text, bringing it quite up to date

The volume is divided into two parts, the first of which deals with the chemical equilibrium of the ions, and the second with the ions, particularly the hydrogen ions, as sources of electric potential differences The first chapter explains the law of mass action and its application to the dissociation of electrolytes and of water The methods of calculating the concentration of hydrogen ions from the concentration of acids and bases in solution and for determining the iso-electric point are explained The second chapter deals with the determination of titrable acidity, pH value and buffer value, while the third chapter, on the dissociation of strong electrolytes, explains the theory of activity and its significance for the pH of buffers The next chapter deals with some complications in the laws of dissociation which arise in connexion with undissociated salt molecules, and in the fifth chapter what is known concerning dissociation in non-aqueous solutions is described

Part 2, Chapter VI, deals with the electrode potentials Nernst's theory of metal electrode potentials is expounded and applied to concentration chains, and especially to gas chains as being the most important for physiological work The biological significance of diffusion potentials, potentials at phase boundaries, and membrane potentials is dealt with in the following chapters, and the volume concludes with a section on adsorption potentials and electrokinetic phenomena Adsorption is explained and the position of the H- and OH-ions in adsorption is demonstrated by using as the adsorbent charcoal, when all cations compete with the H-ions and all anions with the OH-ions The theories of electro-endosmosis and electrophoresis are explained, and their relation to the ionic theory described Diaphragms are also dealt with, and the application of adsorption potentials to physiology and colloidal chemistry is described

As will be seen from the above summary, the volume is concerned mainly with the biological considerations of the subject, but the matter set out is of such importance that no person working in a biochemical laboratory can afford to ignore it Subsequent volumes, particularly those dealing with the technique for the determination of hydrogen ions and its application to various biochemical and medical problems, will be eagerly awaited

Prof Kopaczewski's work covers the same ground with less theory and mathematics. The volume is divided into three parts, the first of which deals with some theoretical considerations, such as the laws of electrical dissociation The section dealing with the measurement of hydrogen-ion concentration contains an exhaustive account of technique, electrical and colorimetric, some even of the very old methods being included Very full descriptions and illustrations of apparatus are given, including that made by the Cambridge Instrument Co In the third part of the book the author discusses the applications of hydrogen-ion concentration in analytical, industrial, biological, and physiological chemistry Its application in biology and medicine is also considered, and although this section has necessarily been condensed, it contains a good account of hydrogen-ion concentration in normal fluids and tissues of the body, and also in certain pathological conditions A valuable addition is the list of buffer solutions, which list includes all the most recent and well-known ones Prof Kopaczewski's book is a complete and reliable treatise on a complicated subject

Prof Austin's little book is concerned with various factors which combine to make the pH constant. The first chapter deals with the general considerations, nomenclature, and the methods whereby the pH of the blood is regulated The last section of the chapter is disappointing, since there is no mention of the acid base equilibrium in relation to gastric and pancreatic secretion, and the renal mechanisms seem to have been overlooked The second chapter is concerned with the normal values of serum, blood, and the body fluids in general. This chapter consists only of three pages, of which one is occupied by a graph ; the normal mechanisms for the regulation of pH might well have been treated more fully, in order to prepare the reader to cope with the third chapter, which deals with abnormal acid base balance Here the introductions of acids and bases into the body are discussed, and also those conditions where excessive losses of acid and base from the body occur There follows a detailed account of the pH of the blood in various diseases Chapter IV. is concerned with the determination of hydrogen-ion concentration by various methods This chapter is hardly full enough to be of practical value, and yet is too involved to serve as a general description of the methods for the non-technical reader.

Throughout the book rather too much is taken for granted ; more details are needed where only mathematical formulæ are given and a fuller explanation of the normal mechanisms would certainly be appreciated But the book remains a successful effort to cope with an extremely difficult task and should increase the interest among clinicians in the basic principles on which modern biochemistry is founded

---

FUNDAMENTALS OF THE ART OF SURGERY

By J. H. WATSON, M B , B S Lond , F R C S Eng , Surgeon to the Victoria Hospital, Burnley London William Heinemann, Ltd. 1926 Pp 349 17*s* 6*d*

Mr Watson has written a book which may be recommended to all who are about to assume the responsibilities of an active surgical career The table of contents would lead us to believe at first that another of the usual text-books of minor surgical matters for house surgeons had been offered to us. This is not so The ground covered is much more restricted than in most books of that type Indeed the volume does not make a strong appeal to those who are looking for a text-book on the details of the technique of minor surgery. The author has a mission of far higher value in his insistence upon the essentials—those ultimate qualities upon which the work of the true surgical artist is based Operating is not surgery, neither is surgery all operating So we find chapters upon the art of surgery, surgical efficiency, surgical judgment, case-taking, and prognosis—chapters which are full of wisdom This is the best part of the book, though elsewhere will be found useful hints on operative technique, after-treatment, the management of shock and hæmorrhage, and other such matters

SURGERY OF THE STOMACH

Die Chirurgie Edited by Prof Dr M. KIRSCHNER (Konigsberg) and Prof Dr O NORDMANN (Berlin) Part X *Die Chirurgie des Magens und des Duodenums* Berlin: Urban and Schwarzenberg 1926 Pp 329

THE high level maintained by previous volumes in this system of surgery is again manifest here Three authors share in the production of this part of the work—namely, Prof N Guleke, Prof H Nieden, and Prof H Schmidt More than 100 pages are occupied by general considerations such as anatomy, physiology, and methods of investigation of the stomach Descriptions follow of the ordinary operations which are employed in gastric surgery, including such little used methods as that of Goepel for carrying out the Billroth I procedure The operation of duodeno-jejunostomy, to which so much prominence has been given by Pierre Duval and D P D Wilkie, receives bare mention An extremely interesting section is that by Prof Schmidt, who has collected all information available on the subject of the alteration of the mechanics of the stomach after resection or anastomotic operations Such knowledge is not so widespread amongst surgeons as its importance warrants The special part of which the remainder of the book is composed gives systematic and complete descriptions of the several diseases It is possible to find full information on any one of them, including the rarer affections such as syphilis, actinomycosis, or volvulus of the stomach or injury to the duodenum, whilst at the end of each chapter is a complete bibliography Sound and unbiased judgment is pronounced upon debatable subjects For instance, under the heading of gastroptosis is given an account of the well-known clinical phenomena of the disease with a review of surgical measures which have been devised for its relief. Though good results from suspension of the stomach were claimed at one time by the author, he does not hesitate to state how unsatisfactory has been the condition of the patients some years later He has abandoned such procedures, but claims to have obtained success in a few cases after performing a Billroth II procedure The same serious consideration is given to the discussion of ulcers of the stomach and duodenum All the available knowledge on the subject has been drawn upon, so that these chapters form a balanced review of the surgery of this disease The reader is the gainer in that the facts are set forth for him to form his own judgment, while definite pronouncements are reserved for matters generally accepted as beyond dispute The section on cancer of the stomach is one of the best we have seen The book is illustrated with some pleasing coloured plates

---

JOURNALS

JOURNAL OF PATHOLOGY AND BACTERIOLOGY Vol XXX. No 1. Pp 1–184 January, 1927 —The Diurnal Tides of the Leucocytes of Man, by A F Bernard Shaw (Newcastle) An account of this paper appears in our editorial columns (p 301) —The Action of Cyanides on Bacteria by F M Burnet (London) Bacteria may be divided into two groups according to their growth—e g , streptococci, pneumococci—or failure to grow—e g , staphylococci, diphtheria, plague, typhoid, *coli*, &c —on media containing cyanide The difference is associated with different types of respiration —Thrombo-angeitis Obliterans, by J Marnoch and Edith MacRae (Aberdeen) A good description of a case of this rare disease, with an account of the anatomy and histology of the leg which was amputated —Infection of Rats by Gaertner's Bacillus, by C Price-Jones (London) If a large number of rats are fed with Gaertner's bacillus a few die and the rest show signs of illness Forty-eight hours after feeding the bacillus can be found in the spleen and liver of nearly all the animals , after about ten days it begins to disappear so that at the end of two months it can be recovered from only 10 per cent. of rats In a minority it survives at least five months. These surviving animals are to all appearances quite healthy, but if they are put to live with fresh uninfected rats they can initiate an epidemic.—The Supposed Presence of a Pressor Substance in the Blood of Patients with High Blood Pressure. by F. R Curtis, A. A. Moncrieff. and S. Wright (London). No evidence of such a substance was obtained.—Neoplasm in a Porose Crocodile. by H. H. Scott and J. Beattie (London) A sarcoma originating probably in the liver with growths in the heart and brain, found in a crocodile from the Malay States at the Zoo —Chronic or Subacute Herpetic Meningo-encephalitis in the Rabbit, with Some Observations on Calcification, by C. Da Fano and J. R Perdrau (London). A chronic form of herpetic encephalitis can be produced in rabbits by using partially immunised animals or an attenuated virus The histological changes are fully described and well-illustrated, and considerable attention is given to the apparent calcification which is found in nerve-cells and other structures The disease bears a considerable resemblance to encephalitis lethargica in man.—Complement Fixation with Bilharzia by N. Hamilton Fairley (Bombay) Alcoholic extracts of bilharzia cercariæ in its molluscan hosts act specifically in complement-fixation tests. As far as can be made out they are free from protein. They are also effective as antigens when injected into goats. Infected goats give a much quicker and larger antibody response than normal animals so that the method may be used in diagnosis —On the Relation of the Alcohol-soluble Constituents of Bacteria to their Spontaneous Agglutination, by P. Bruce White (London). The ‘rough” variants of the food-poisoning bacteria generally agglutinate spontaneously in salt solution of ordinary strength After extraction with hot alcohol, chloroform, or ether, emulsions are stable, but their sensitiveness to salt can be restored by impregnating them with the alcoholic extract. The alcohol-soluble material itself is soluble in distilled water, but is easily precipitated by the addition of salt.—The Rapid Death of the Meningococcus and Gonococcus in Oxygenated Cultures. the Part Played by the Development of an Unduly Alkaline Reaction, by H V. Phelon. Georgina M. Duthie. and J. W. McLeod (Leeds) The production of considerable quantities of acid in bacterial cultures is well known ; an inhibitory or fatal amount of alkali may also appear under certain conditions, due in the main to ammonia and alkaline carbonates arising from the oxidation of sodium salts of fatty acids — Observations on the Sonne Dysentery Bacillus and *Bacillus coli anærogenes,* by D Nabarro (London). The Sonne bacillus has been isolated under other names for some years in this country in children's diarrhœa and other conditions —An Epidemic of Fowl Typhoid, by S Miller and F. B Smith (Harrogate) An account of a widespread epidemic of this rather uncommon disease in Upper Nidderdale, in which *Bacillus sanguinarium* was isolated —Some Observations on Streptococci Occurring in Children, by Vida J. Perry (London). *Pyogenes, mitis. fæcalis, salivarius.* and *infrequens* were the chief varieties met with in a mixed collection of diseases —Prophylaxis of Measles with Convalescent Serum, by S Miller and F. B Smith (Harrogate). Gives an account of the successful application on a small scale of this method.—Leptothricosis. by I. Mackenzie (Glasgow) Description of the pleomorphic leptothrix organism isolated from the cerebro-spinal fluid of ten cases of this obscure disease which is becoming susceptible to diagnosis —Observations on the Relative Value of the Wassermann and Kahn reactions in cases of Congenital Syphilis by D McClean (London). A study of 767 tests supports the delicacy and accuracy of the Kahn reaction.—Obituary notices of John George Adami (with portrait and bibliography) and William Edward Marshall —Proceedings of the Pathological Society of Great Britain and Ireland.

JOURNAL OF PHYSIOLOGY. Vol LXII, No 1. Cambridge University Press. 12*s* 6*d*.—The Arterial Pressure in the Eye. by W. S. Duke-Elder. The author measured the pressure in the branches of the retinal artery of anæsthetised cats and the pressure in the ophthalmic artery. No method has yet been devised to measure the capillary pressure in the eye. but it is probable that in the arterial capillaries it rises at least 30 mm. Hg higher than the pressure in the chamber of the eye—i e , to about 50 or 55 mm. The vascular pressures although by themselves they prove nothing, make it possible that the aqueous humour is formed purely by a process of dialysation. —Insulin and the Production of Acetone Bodies by the Perfused Liver, by H S Raper and E. C. Smith. The isolated dog's liver when perfused with defibrinated blood has been shown to produce small amounts of acetone bodies, but much larger amounts if ammonium or sodium butyrate is added to the blood. The authors' experiments were designed to gain an insight into the anti-ketogenic action of insulin. which in severe diabetes stops the formation of acetone bodies. By experiments described it was found that a cat's liver in situ when perfused with its own blood produces acetone bodies in quantities proportional to the fat content of the liver. and inversely proportional to its glycogen content. No evidence was obtained that insulin influences this action of the liver. The increased production of acetone bodies following addition of sodium butyrate to the blood is unaffected by addition of insulin About 80 per cent of the theoretical acetone is obtained from sodium butyrate added to blood perfusing the liver. There was no evidence that in the isolated perfused liver insulin causes a deposition of glycogen even when the concentration of blood-sugar is several times as great as normal. or that it causes increased glycogenolysis The perfused hind limbs of the cat remove glucose from the blood much more rapidly when it contains insulin than when it does not. but this effect is inhibited when pig's blood is used for the perfusion. A method is described for the estimation of butyric acid in blood.—The Impulses Produced by Sensory Nerve-Endings. Part 4, Impulses from Pain Receptors by E. D. Adrian The author analyses the impulses set up in cutaneous nerves by painful stimuli and compares the pain discharge with that of other receptors. The older view that pain resulted from excessive stimulation of any cutaneous receptor has been largely abandoned in favour of the idea of special pain receptors and conductors. Impulses produced in cutaneous nerves by painful stimuli to the skin have been recorded in the cat and in the frog. By the use of a sharply localised stimulus (the prick of a fine needle) the number of fibres in action can be restricted so that individual impulses are recorded without interference. With a constant stimulus (the needle pressing with a constant weight on the skin) the frequency of the discharge declines rapidly from its initial maximum value. With an increasing stimulus (the needle being slowly driven through the skin) the frequency rises gradually and declines again when the movement is *stopped*. The intensity of the pain sensation in man follows much the same course. The impulses produced by the pain receptors have the same time-relations as those produced by pressure receptors (cat) and muscle receptors (frog). The frequency of discharge in each fibre seems to cover the same range and there is nothing characteristic in the grouping of the impulses. The only distinction that can be drawn between the discharge of the pain receptor and that of other receptors lies in the very brief discharge with weak stimuli. It is suggested that these brief discharges may not be adequate to evoke the pain response but may serve instead for momentary sensations of contact. the development of the pain response depending on the summation of impulses in the central nervous system. Since the range of frequency of each fibre is much the same for all the receptors investigated it is presumably determined by some common factor. such as the properties of the naked axis cylinder, and not by the particular structure of the end-organ —On the Cellular Mechanism of Bile Secretion and its Relation to the Golgi Apparatus of the Liver Cell, by W Cramer and R J Ludford In the cells of all secreting glands except the liver the specific products of secretion are passed out of the cell in one direction only But the cells of the liver pass glycogen into the blood stream and at the same time take up bile-pigments and bile-salts from the blood Each cell thus subserves an internal and external secretion The authors' observations lead them to conclude that in the liver cells the bile constituents appear as a secretion within the Golgi apparatus, which in the process of bile secretion first enlarges and then fragments The fragments are dispersed through the cytoplasm and reach the periphery, where they pass their contents into the intercellular bile capillaries —The Sensitising Action of Alkalies, by A Hemingway. That the tone and activity of tissues containing plain muscle is largely dependent on the reaction of the fluids bathing them has long been known, and there is evidence that certain drugs are more effective when used in an alkaline medium The author found an increasing reaction of mammalian blood-vessels, uterus, and small intestine to successive changes in pH towards the alkaline side An exaggerated response to adrenalin accompanies the reaction to alkalies —Reversal of the Action of Adrenalin, by B A McSwiney and G L Brown The type of response produced by adrenalin is related to the condition of tonus of the gastric musculature of the rabbit, an inhibitory response being obtained in the tonic or contracted muscle, an augmentor response in the atonic or relaxed muscle —The Application of the Ethyl Iodide Method to the Determination of the Circulation-Rate in Women, by Winifred C Cullis, Olive Rendel, and Ellen Dahl The stroke-index gives an average output for Women of 1 7 c cm per kg of body-weight from the right side of the heart during rest —The other papers are the Effect of CO_2 on the Absorption of Alcohol and the Influence of Alcohol on the Diffusion of CO_2 in the Small Intestine, by N Edkins and M M Murray —The Differential Paralysis of Cardiac Nerve-Endings and Muscle, by W R Witanowski —The Buffering Power of the Blood of *Maia* Squinado, by Phyllis M Tookey Kerridge —The Recovery Heat Production in Tortoise Muscle, by W Hartree and G Liljestrand —The "Interference" of two Flexion-Reflexes, an Examination of Vészi's Experiment, by T. Graham Brown —The Effect on the Chronaxie of Thyreo-parathyroidectomy, by N Douglas Buchanan and H S D Garven

ARCHIVOS DE LA CLINICA MEDICA Del Prof E Prado Tagle, Santiago, Chile 1926 —This volume is the first of a series of clinical reports which Prof Tagle hopes to issue to illustrate the work done in his clinic For six years he has been engaged in bringing the clinic up to date and making it worthy of the principal hospital in the capital of Chile It now has a well-equipped laboratory besides a policlinic which supplies the wards It is interesting to note that the whole has been organised on a contributory basis, both in- and out-patients always giving something unless quite destitute, the proceeds are shared between the staff and hospital, and the system is said to work well The clinical articles include one by Prof Tagle on endocarditis lenta, an exhaustive examination of German views on the nephropathies by Dr R Vicuna Herboso, and about ten other contributions by members of the staff, all illustrated from the clinical work of the hospital The volume is well printed and produced, and promises to be the prelude to an interesting series of records

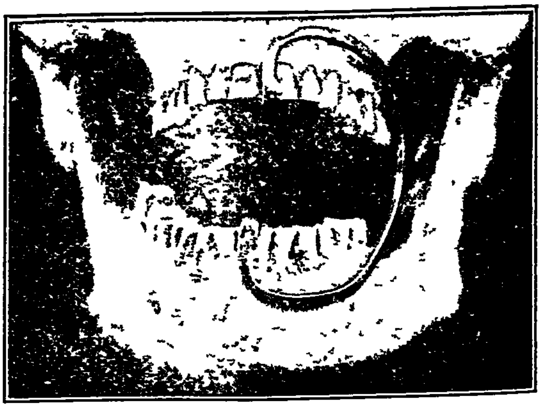
New Inventions.

A NEW MOUTH PROP

OPERATIONS upon the teeth, mouth, and throat under an anæsthetic require the use of some kind of prop to hold the mouth open I do not know of any device for holding the mouth open which is entirely satisfactory Those in general use have many serious faults They are liable to slip, they get into the way of instruments, they obstruct the view and, in the case of extraction of teeth, necessitate the use of the Mason's gag if teeth on both sides of the mouth are to be removed The mouth prop described here leaves the mouth entirely unobstructed, and it cannot possibly slip Practically any tooth on either side can be extracted without interference by the prop

The device consists of an open frame made of oval wire, shaped so that it lies in the sulcus between the cheek and the jaws at the top and bottom of the mouth The front ends of the frame are bent to form rests for the edges of the upper and lower incisors When in position the frame lies inside the cheek, between the cheek and the gum over the apices of the teeth and is right out of the way, as will be seen from the illustration

The illustration shows the mouth prop in position on a skull Being smooth and polished the prop slips into the mouth quite easily When in position the cheek keeps it there, and should the mouth be opened wider the prop does not move or get out of place I have found that patients, as a rule, prefer it to the ordinary gag, as there is nothing for them to feel with the tongue A piece of rubber tubing is pushed over the ends where the teeth rest, and the whole thing is simple and easily sterilised Three sizes are necessary for all ordinary cases, and it can be used on either side of the mouth It can also be made for cases where the upper or lower incisors are missing, the hook in this case being replaced by a flat pad to rest on the gum For surgical purposes it can be made for use in edentulous mouths by having two gum rests instead of the hooks



I have used it frequently in my practice and found it extremely useful, extractions of the four first molars being made very much easier, especially if the anæsthetist is not too expert with Mason's gag For operations on the tonsils and throat I should think it would be ideal. It is also useful in the case of very young children, as it is impossible for them to push it out with the tongue or to move it without putting the hand to the mouth There are, of course, certain cases where it would not be suitable, as when the incisors only are to be extracted, or when the jaws are abnormally shaped, but for the majority of cases I think it will be found to be a great improvement upon the types at present in general use

INFLUENZA.

AS the nose and throat in this disease are the only routes of infection, it follows that the organism should be easily destroyed or attenuated by an insufflation powder of high bactericidal value. This is now readily available in the form of Dimol Snuff.

This Snuff is guaranteed to be equal in bactericidal value to 20% pure carbolic acid and to be perfectly free from all deleterious action on the mucosa. As a prophylactic measure the use of this powerful non-toxic powder is clearly indicated.

A nose and throat specialist of 30 years' experience, who has been prescribing Dimol Snuff for over two years in the disinfection of the nares and naso-pharynx, writes :—

> "This Snuff, taken three or four times a day during an epidemic of influenza, should be a perfect and pleasant preventive to the insidious settlement of the pervading bacillus in the nose and throat"

As the above remarks apply with equal force to the prevention of Infantile Paralysis, Dimol Snuff should prove most helpful as a preventive for this new menace to school life.

Samples and Literature will be sent on application to the

THE PAYING PATIENT.

ONCE again we are reminded by outspoken words from a prominent medical man of the inevitable changes which are lying ahead in the administration of our voluntary hospitals. and some of these changes need no longer be called inevitable, for they have passed beyond such a stage and have begun to occur Mr R G HOGARTH, the President of the British Medical Association in the short address on the future of voluntary hospitals, which is published in another column this week, sets out the present position. with attractive arguments for its reform in certain directions, and he will find few to gainsay the words that he has spoken, but many may wish that he had allowed himself time to consider more fully the position of the paying patient, whose arrival, as a serious proposition in hospital management, he notes, and whose more frequent occurrence he prophecies on the strongest evidence

The practical difficulties inherent in the introduction of the extension to paying patients of the amenities of the voluntary general hospitals will not prevent their increasing presence One of these—namely, the avoidance of all risk lest beds upon which the poor have absolute claims may be filled by more prosperous patients—is a matter which we look with confidence to see cared for in the strictest manner by all hospital committees, in conjunction with all hospital staffs Strict supervision and much tact are here required, but the right procedure can be ascertained in most cases, and the public may feel assured that the grand charity of the institutions will never be allowed to undergo curtailment But a completely new difficulty in hospital administration is brought about with the appearance of paying patients From those who had nothing nothing was expected to them all was given, and given with the lavish attention that was implied in the subscriptions and donations of the public The public gave the money, the medical workers gave all else With the introduction of paying patients, the question of what should be paid for arises, and here we have a difficulty to meet which no common pattern has been devised, so as to be followed by either the medical or the lay administration of the hospitals, nor have the ramifications of the difficulty been thought out in detail or made the subject of any authoritative advice In true British style we have got into the middle of the situation before designing the best ways out, equitable solutions of the various problems will arise, not, perhaps, uniformly but none the less well adapted to meet different emergencies, but so much evidence of the growth of pay-wards is now available that some orderly plans to meet the position as it arises, would be welcome Certain sound proposals have received concrete form in decisions of the Representative Body of the British Medical Association but we do not know of many hospitals which regulate by these the admission of private in patients The circumstances that have brought about the demand for paying wards in general hospitals and for the establishment of paying hospitals need no description—all are familiar with the big underlying facts First, a vast class of patients, having no claim on charity, and not dreaming of putting one forward, cannot meet the expenses accompanying many serious illnesses, and secondly, for certain of these illnesses, whatever the private means of the patient, institutional treatment is the best course Accordingly pay-wards are widely needed and being provided At the end of last year a report on the voluntary hospitals of Great Britain appeared, in which Mr R H P ORDE, the acting director of the hospital service of the joint Red Cross Council, gave some notable figures By these he showed that in a grand total, composed of nearly 39,000 beds in general hospitals, and 7300 in special hospitals, 75 per cent of the institutions had a credit balance while the payment by patients, either of the full or partial costs of maintenance, or by certain direct weekly fees, was playing a considerable *rôle in bringing* this favourable position about This is a tale of moderate success, and even of great success when the position is compared to that of the previous decade, but in the favourable struggle to maintain solvency no provision is made for large and inevitable capital expenditures, to meet which grants and subsidies must still be hoped for Certainly there is no surplus here which can be relied upon to provide any payment for medical service, if it should be posited that paying patients have a right, after the preferential claims of the poor have been met, to all the amenities of hospital service upon payment of establishment charges only

This situation cannot be expected to escape professional attention, it has been much before the eyes of medical men, but regularly eludes those of the lay public Modern medicine and surgery are day by day being made more available to every class of the community, but while the prime reason for the existence of voluntary hospitals will not be lost sight of, the relations between the public and their medical advisors must not be weakened The value of these relations is spoken of in terms of money when the question of fees is debated; but money does not represent the essential value, although it is the element which forms the convenient subject for discussion here The patient whose means allow him to go to a private nursing home does so with complete freedom and choice as regards the services of his physician or surgeon, in many cases he remains in the care of his own private practitioner who calls in such consultant advice as he deems wise. The connexion other than that of fees remains undisturbed While it would be impossible for such a system as prevails in these homes to run concurrently with hospital routine in a general hospital, will it be feasible for it to remain in force in paying wards attached to a general hospital? If not, paying patients may lose forms of coöperation in their treatment which would prove salutary, and retention at home may be insisted upon where every feature in the case calls for institutional care We have here but one problem of many which the arrival of paying-wards heralds, but it is one of importance

FEE STANDARDISATION.

LATELY a judge in Belfast has decided that a doctor is not entitled to grade his charges according to his patient's means Capacity to pay, it seems on this judgment, must not be taken into account, the doctor must place rich and poor upon an absolute equality when he makes out his charges Is this the idiosyncrasy of an individual judge, or do the law courts begin to perceive a change in public opinion which future decisions must reflect? At present there is a legal implication that a professional man is to be paid for exercising his professional skill If no figure is agreed beforehand, the law courts will allow him to recover what is just and reasonable If any scale of charges is established as customary, that scale will be taken to be just and reasonable General practitioners have undoubtedly established the custom of grading their fees according to the patient's income, the income being roughly estimated by the supposed rental of the house This time-honoured arrangement has for many years been recorded, amongst other places, in the pages of "Whitaker's Almanack," where the relation between house rent and fees (still expressed in the old pre-war values) is published in parallel columns for the information of the public The principle involved in these figures has not been challenged, it is regularly advanced as an accepted one in the unfortunate case of a legal dispute about medical fees, and judgments adverse to practitioners have been founded without exception, we think, upon other circumstances than the consideration of the charges in combination with the house-rent paid Perhaps the principle was, in part, developed from the ancient notion—applicable still to the fees of the barrister, though no longer applicable to those of the doctor—that professional remuneration is a honorarium, or, to descend from the fine Latin word to colloquialism, a tip, it would be surprising if a railway porter reckoned his expectations on the same scale for the first-class and the third-class traveller Judges have not hitherto rejected the principle that medical fees should be graded according to the patient's income, and they have been known to give definite support to the subsidiary, or perhaps converse, principle that a practitioner living in a district frequented by professional leaders, or where rents and other expenses are heavy, may charge a higher fee than one living in a country village It may be taken, we think, that, whatever the historical basis for the procedure may be, it is generally conceded that medical fees, in the public and professional interest alike, can be graded in a general way upon the pecuniary position of the patient as judged by his residential status

But this method of charging is, of course, one of rough justice, and the appearances of material prosperity are often deceptive Here the practitioner, to the great comfort of both parties, may sometimes be able to have the situation made clear by a mutual arrangement, although this is not as simple an affair in general practice as in consultant work The fee of the consultant is very usually settled, after an interchange of confidences between the patient and the general practitioner, in the case of a particular service No such rosy opportunity arises for the family practitioner to arrive at what should be his own charges for general and perhaps prolonged attendance The specialist can maintain his fixed scale of fees, ascertainable in advance Like the fashionable advocate in the law-courts, his fee may be high because his services are in high demand, though, unlike the barrister, he cannot manage to attend to several cases simultaneously The general practitioner is in a different position, his situation indeed must be unique among professional men He can hardly refuse his services; he can hardly haggle with his patient on the doorstep, and he cannot exactly foresee the nature of the work which he is about to undertake When it is remembered that the patient ultimately receives an account which comes to him retrospectively as a total of items, neither checked nor agreed, it is significant that the doctor's bill is so seldom questioned

Are we approaching a change of method? House rentals no longer furnish so good a guide to the assessment of income as in the days when large houses were more readily inhabited The panel system is gradually accustoming a large proportion of the medical profession to the rigid tariff of scheduled charges If and when the whole of our population is treated by a State medical service—which some expect and of these some hope—fees will either be standardised or entirely abolished Meanwhile, in grading his fees according to the capacity to pay, the medical practitioner does but pass on to his patients the system applied to himself as a payer of rates and taxes

◆

THE EDUCATION OF THE DEAF IN THE UNITED STATES

A REPORT of a visit to American schools for the deaf, paid in 1923 by Mr SIBLEY HAYCOCK, headmaster of the Langside School, at Glasgow, gives valuable information on the subject It has been published by the National Association for the Oral Instruction of the Deaf, in association with the National College of the Teachers of the Deaf, and should prove of great utility to educational workers along similar lines in this country, for it summarises the position in the States and indicates directions in which advances may be reasonably expected in the future on both sides of the Atlantic Mr HAYCOCK gives a general review of the chief features of education of the deaf in the United States, and in places where he has found it impossible to combine a broad view with mention of details he supplies references or addresses so that further information can be obtained from American sources He points out that, as in America education, general and special alike, is a function of each separate State and not of the Federal Government, many educational units perform their functions through many legislative boards in determining the rules and policy for the training of youth, a fact which renders it hard to justify general statements regarding the education of deaf children as a whole in the United States All the States in the Union, with the exception of Wyoming, Delaware, Nevada, and New Hampshire maintain, either wholly or partly, residential institutions for the education of the deaf children, while "Gertrude" and her little friends can resort, at the expense of their separate States, to the nearest State-supported schools in their proximity There are 64 public residential schools, of which 45 are entirely supported by the States in which they are respectively situated, while the remaining 19 are partially subsidised from the funds of the State, or from school fees or voluntary contributions The State, however, obtains little private relief, for only 11 institutions have fee-paying pupils, while 13 receive partial support from voluntary sources Here there is room for improvement When the geographical area and population of the United States are considered, the provision for the education of the deaf subject will not be found very large as far as residential institutions are concerned, but there are 78 public day schools for the deaf in the States, the majority of which are supported either by the State or by the city in which they are to be found, with or without public subsidy, and Mr HAYCOCK was impressed by the size of some of the institutions But all with practical experience of imparting instruction to large classes know the difficulty inherent in them, which must be accentuated when the pupils are not of either normal or comparable standards There are in America residential schools for the deaf where pupils ranging from 7 years to 23 years, or older, are gathered together under a single roof, and it is obvious that here great changes in the grouping of pupils of such dissimilar age must take place before organisation can be evolved dealing with many of the problems that are presented It is good to know that more individual and homelike attention is being provided by progressive centres

The chief support of all the institutions depends upon the "appropriations," as they are styled, and the usual procedure seems for the State Board of Education to obtain a grant by vote of the State legislature, and to apportion the results to the various institutions under its ægis according to the several needs in each category, when, as may well happen, a particular institution does not secure the amount for which it has budgeted a "deficiency appropriation" is provided This is an excellent method of meeting the financial needs, and it is to be hoped that the principle prevails under which help is given in proportion to the amount of self-help manifested It would be excellent that similar appeals, partly State and partly popular, were feasible in this country where the need is equally sore For the similarity of conditions prevailing in the City of New York and in "County Council London" is brought out by the following comparison the money appropriated for the education of deaf children attending the New York City day school, taking the average for the two years, April 1st, 1921–March 31st, 1923, works out for 358 pupils at £84 per child per annum; while the cost of educating 340 deaf children at the London County Council day schools during the same two years works out at approximately £80 In both cases an average attendance was assumed, but it must be remembered that a majority of the American States have no compulsory law enforcing the attendance of deaf children at school, while the arrangements in those States where compulsory legislation is in effect are not uniform Some degree of difficulty in getting the deaf population into school at the desired age appears to be experienced throughout the States, despite the efforts of sympathetic workers, and failure to provide early education for the children is made the subject of some critical remarks But the report records that every deaf child in the United States is assured of a good elementary education, and further has an opportunity for receiving secondary and even college training when capable of profiting by them The problem of how to ensure the early education and instruction of these afflicted children remains largely to be dealt with Pupils who can justly aspire to a college education will find their needs catered for at the Gallaudet College for the Higher Education of the Deaf at Washington, and it is a good testimony to the way in which Mr HAYCOCK has done his work that the foreword to his book should be a criticism of it from Prof I S FUSFIELD of that College, and editor of the "*American Annals of the Deaf*" Prof FUSFIELD finds Mr HAYCOCK's report "an open-minded, outspoken review, correctly focused," and recognises that a careful study of it is needed, because "it has sought out the pertinent facts in the American plan, and analysed them constructively"

An epitome of the curriculum for the pupils at Gallaudet, where the students at the time of Mr HAYCOCK's visit numbered 134, states that 130 of these were drawn from the residential institutions for the deaf, and represent approximately 3 per cent of the sum total of pupils of those schools Applicants for admission are only admitted to the preparatory class when well grounded in elementary studies, especially in mathematics The charge for board, lodging, and tuition is 500 dollars for the academic year, but there are opportunities for the students to earn part of this money by labour in the College and without—a certain number of the male students, for example, are employed in the printing offices of Washington A degree is offered to Gallaudet students after three years' study, when it is to be remembered that vocational training receives particular attention By reason of the longer school period prescribed in America than in England the education of deaf children seems in advance of that point which the education of the English deaf children reaches, and results at the best of the residential schools, especially in the Eastern States, are, age for age, better in America than with us But Mr HAYCOCK does not attribute this entirely to the extended period of education or to the longer school hours, but points to the superior organisation of the institutions, their better equipment, and their better staffing None the less, it appears from other sections of the report that the supply, training, and certification of teachers remain for the American schools, as for ours, a serious problem.

Annotations.

"Ne quid nimis"

THE SALE OF PHENOLIC DISINFECTANTS

THE pharmaceutical press has for some time been exercised over the question of the sale of disinfectants by oilmen, grocers, and similar tradesmen The qualified pharmacist appears to suffer under a real grievance, which in fact involves the whole question of the use of disinfectants Why do people use disinfectants? It would probably be difficult to obtain from the average user a clear answer to such a question There is no doubt a widespread and rather touching faith in the hygienic properties of anything possessing a phenolic or tarry smell It is, perhaps, on the whole as well that this should be so, but there is some danger that a false sense of security may thereby be engendered and also that the free use of disinfectants may be considered as a substitute for cleanliness Further, the experience of the past shows that there is definite risk in the unrestricted sale of substances which from their very nature must be more or less poisonous to human beings and domestic animals This danger has been recognised by the Pharmaceutical Society and the Privy Council, the bodies on whom the legislature has placed the onus of safeguarding the public in such matters By the Pharmacy Act of 1868 chemists and druggists were given the monopoly of the sale and dispensing of scheduled poisons—a work which, it will be understood, forms but a small part of the practice of the average pharmacist. The addition of substances to the schedule of poisons as occasion might arise was left to the initiative of the Pharmaceutical Society with ratification by the Privy Council No undue haste appears to have been shown in the matter of the inclusion of carbolic acid since the Pharmaceutical Society, moved thereto by the representations of coroners regarding the alarming number of accidents and suicides, passed the necessary resolution in 1882, and carbolic acid was scheduled in 1900 Many deaths took place in the interval largely due to careless sales By Orders in Council of Oct 1st, 1911, and Oct 12th, 1912, made under the Poisons and Pharmacy Act, 1908, all liquid preparations sold as carbolic, or carbolic acid or carbolic *substitutes*, or carbolic disinfectant, containing not more than 3 per cent of phenols shall be labelled "Poisonous—*not to be taken*," although, unlike stronger preparations, they need not be labelled "Poison," nor is the sale confined to registered pharmacists This allows a variety of products of no great germicidal value to be sold by whosoever desires so to do The liberation from German proprietary rights of the word "lysol" in 1914 enabled anyone who wished to apply this name to any product which he felt he could advantageously sell as such One result is that whilst several firms of repute make, for use by physicians and surgeons and for sale by pharmacists, preparations similar to the original lysol, other preparations are about one-sixteenth its strength That is, they are sufficiently weak to be sold by anyone The following shows that this cannot always be done with impunity A case heard at Bow-street in 1925 led Mr Graham Campbell to the decision that by usage of the trade the word "lysol" had come to mean a solution containing 50 per cent of cresols Hence he must hold that a false trade description had been applied to the article, and that the article had been sold bearing such false trade description The defendant company was fined 15 guineas on each summons with 50 guineas costs, and the retailers were treated under the Probation of Offenders Act, only being required to pay 5 guineas costs It was then suggested by the defence that this action was an attempt by pharmacists to prevent the sale of lysol by grocers

What, it may be asked, is the proper scope of phenolic disinfectants? There is a definite surgical use for sterilising dental and general surgical instruments, cleansing areas to be treated, wounds, and sponges For this work lysol is specially convenient owing to its transparency In addition to metal instruments, rubber gloves and sheets, the walls and floors of operating rooms, and all sorts of things which have been or may have been in contact with patients suffering from infectious disease need actual sterilisation, as do stools, urine, and other emanations of such patients All these are well-defined medical and surgical requirements for which it is necessary to have a clear notion of the strength and general character of the disinfectant used Where a patient is not treated at a hospital or clinic, much of the less critical work is necessarily left to the members of the household, who act under the general instructions of the doctor in charge of the case It is important, therefore, that if he orders a certain material to be used, the description should be sufficiently precise for him to know that it or its equivalent shall be obtained In addition to these definite uses many people seem to prefer disinfectants to absolute cleanliness, so masking a fetid smell with a phenolic one where the right thing would be to have no smell at all Public bodies are not exempt from blame in this matter, and although it may be argued that where it is impossible to secure cleanliness disinfection is the next best thing, yet it is difficult to see, in face of the known properties of phenol, that the sprinkling of a little carbolic powder or fluid on a garbage heap will do more than arrest decay on the surfaces actually touched by the disinfectant, whilst the bulk of the material may be fermenting and giving off foul gases and vapours

Some useful and suggestive work on the composition and properties of a variety of disinfectants, mostly phenolic in character, was published by the Medical and Health Department of Western Australia in 1924 In addition to pure carbolic acid, nine proprietary articles of the lysol group — cresol-soap solutions containing about 50 per cent of phenols, with one made from 50 per cent orthocresol and soft soap, four weaker lysol-like preparations, seven emulsified preparations, and four "phenyles" (emulsion-forming preparations of low phenol content, low cost and small bactericidal power)—were examined Tested against the same strain of colon bacillus in distilled water, the average coefficient of the 50 per cent lysol type was 2·4, of the weaker "lysols" from 0 2 to 1 6, varying with the proportion of cresol, whilst the emulsions averaged 8 4 The presence of only 3 per cent of fæces, however, necessitated in all cases an increase in strength of the solutions for the same effect to be produced Whereas the proportion of carbolic acid had to be raised 1 4 times, the cresol soap solutions needed to be raised 2 4 times, and the emulsions about 8 2 times for the same effect to be produced These results show that for sterilising clean instruments, or inert things like rubber gloves, dilutions based on the coefficient may be used But the presence of much organic matter of a kind which may form condensation products with phenols renders it necessary to use much stronger solutions than a consideration of the coefficient would suggest, and incidentally greatly decreases the value of the apparently more active emulsified liquids These facts make it all the more necessary that a medical man in advising as to the use of disinfectants should not only consider exactly what is appropriate, but should indicate that it *must* be obtained, making it clear that only pharmacists are allowed to sell preparations of the required activity

ADMINISTRATION OF VACCINATION

WE publish in this issue (p 271) an address by Dr James Bennett, delivered at the annual general meeting of the Association of Public Vaccinators on Jan 28th, on his retirement from presidency of the Association In this address he discusses impending changes in the administration of vaccination, dealing with its anomalous position under the Poor-law and the proposed transfer to the county and borough councils The pros and cons of this reform are fairly set out, and some of Dr Bennett's arguments are applicable to different but related problems which are likely to arise out of the Government's new Bill On the whole he considers that the proposed change would advance the cause of vaccination and improve the position of vaccinators It should also be welcome, he thinks, to the medical officers of the counties and boroughs, if only because it simplifies the machinery for general vaccination in the face of an epidemic Dr Bennett believes it to be very inadvisable, however, that vaccination should become the duty of assistant medical officers of health, pointing out that these officials often hold their posts for only a short time, and cannot get to know families and parents in the way that a public vaccinator should In the discussion which followed Dr Bennett's address there was almost unanimous agreement that the change of administration to counties and county boroughs would be in every way desirable, though some speakers expressed the opinion that it would be still more satisfactory to serve directly under the Ministry of Health There was a strong feeling that fixity of tenure and the question of superannuation should be kept prominently in view during discussions of the Government's Bill

REGIONAL DENTAL OFFICERS.

THE Ministry of Health announces the first appointment to the panel of dental surgeons who are to advise approved societies under the National Health Insurance Scheme in their annual allotment of over £2,000,000 for the provision of dental treatment as an additional benefit This panel will enable the societies to obtain a second opinion as to the need for such treatment, to check estimates of cost received from dentists, and to standardise the materials supplied. There are to be six full-time regional dental officers in England and Wales, who will be stationed at London (2), Birmingham, Manchester, Leeds and Cardiff The appointments just made are Mr H A Mahony (Principal Regional Dental Officer) and Mr. Arthur Taylor in London, Mr J Woodford-Williams in Cardiff, Mr H G H Cowell and Mr T Dilks Page One other appointment has yet to be made The cost of the service is to be met out of the funds of approved societies providing dental benefit under the new arrangements, which have been agreed upon between representatives of the societies and the dental profession

THE FINGER-PRINTS OF IDENTICAL TWINS

A NOTE in our columns on Dec 25th 1926 referred to an interesting paper by Dr G P Crowden published in the Guy's Hospital Reports the previous October, and drawing attention to the remarkable similarity in physical make-up and mental development which characterised a pair of male twins who had come under detailed investigation Their size, shape, appearance, rate of growth, finger-prints, differential blood counts, illnesses, scholastic records, mental characteristics, muscular power, and all measurable qualities were compared, and a remarkable degree of resemblance was revealed The similarity of twins may lead in real life to many embarrassing and even sensational situations, while since the days of Terence it has furnished material for the plots of dramatists and story-tellers, it is a subject, therefore, which always leads to general discussion This has occurred in respect of Dr Crowden's twins, and our reference to the resemblance of their finger-prints has been translated by the press into a statement of absolute identity Dactylography is such a powerful weapon in legal hands, that the Commissioner of Police of the metropolis has received inquiries from finger-print experts all over the world, calling attention to the statement in various newspapers, that the finger-prints of these twins had been found to be identical, and asking for particulars As a result the Commissioner has replied to these inquiries, by pointing out that the finger-prints of these twins are not identical, and, further, that Dr Crowden had never made any assertion to that effect, contenting himself (as in our columns) with stating that they were "very much alike" Reproductions of the impressions have been obtained by New Scotland Yard and examined, with the result that the ridge characteristic data disclosed were found to be absolutely dissimilar The estimation of finger-prints is a very exact procedure, and it is clear that a superficial resemblance may conceal fundamental variations

DIURNAL TIDES OF LEUCOCYTES

IN his *Ars Anatomica* of 1714 the ingenious Dr Salmon engages in a discussion of the rate of the circulation in man Perceiving that he can obtain his answer if he knows the blood volume, cardiac output, and pulse-rate, he calculates that a man has (in modern measures) about 11 litres of blood, and that the left ventricle expels about ¾ c cm at each systole, and observes with his minute watch that the heart beats about 60 times a minute Whence he deduces that all the blood in the body goes round once in about four hours Horrified at such a violent and extravagant motion, he concludes by satisfying himself that it is much more agreeable both to nature and reason to believe that the blood ebbs and flows in harmony with the sea, and circulates twice every 24 hours We know now that it goes round once a minute, or rather faster, when the body is at rest, but this naive confidence in the harmony of man with all nature is recalled by an interesting study of the fluctuations in the number of leucocytes in the blood by Dr A F Bernard Shaw, of Newcastle, which appears in the current number of the *Journal of Pathology and Bacteriology* Dr Shaw finds that the total leucocyte count may vary by 1000 or 2000 at short intervals—15 minutes or even less—and that these small oscillations are imposed on two main tidal waves, one reaching its maximum in the afternoon, the other soon after midnight These changes are due to fluctuations in the number of neutrophile cells, and the lymphocytes and other varieties are not involved, he also produces evidence that the leucocytes are uniformly distributed in the peripheral and central circulations What is more surprising, however, is the discovery that the day and night tides occur regardless of food, exercise, and sleep, which have no clear influence on them; nor are the curves of leucocytes synchronous with the daily curve of body temperature It is shown once more that "digestion leucocytosis" is imaginary, and we hope that myth is now exploded for good But the leucocyte tides are left in a mysterious state, and it still seems likely that the apparent *independence* of food and sleep would disappear with a longer trial of an inverted mode of life It takes time for cells to multiply and grow, and rhythmical habits impressed on tissues by immemorial rhythms of personal and ancestral conformity with the clock may well last through the trivial irregularities introduced by experiment

THE WEBER COLLECTION

THE first two volumes of the great collection of Greek coins formed by the late Sir Hermann Weber, M D, were reviewed in THE LANCET on their appearance[1] The first part of the text of Mr Forrer's third volume[2] has now appeared, together with a portfolio of plates to illustrate the whole volume The coins dealt with in this portion (Nos 4744 to 6067) are those of the seaboard countries of Asia Minor from the Bosporus to Lydia, and they are illustrated on Plates 172-247 We have already mentioned the fact that by means of a special grant from the Treasury, many of the most noteworthy coins in the Collection have been acquired for the British Museum This provision has been supplemented by a grant from the National Art Collections Fund, by the generosity of private individuals, and not least by the generous opportunities for pre-emption offered by Messrs Spink and Son The extent to which the National Collection has been enriched can nowhere be better illustrated than from this section of the catalogue Among the most beautiful of ancient Greek coins are the rare gold staters, dating from the early fourth century B C, of the celebrated Hellespontine city of Lampsacus The Weber Collection contained no less than nine of these staters, of which two are unique, two known only by one other specimen of each, and a fifth known only by two other specimens All five coins are now in the British Museum, including a remarkable coin which has for type a Nike sacrificing a ram

Farther along the coast of the Propontis was another of the big coin-producing cities of antiquity, the town of Cyzicus, whose electrum staters took the place of an international gold currency during the centuries before Philip of Macedon opened the Pangæan gold mines, and Alexander the Great after him sent the great stores of gold from his Eastern conquests into currency This electrum is a natural alloy of gold and silver washed down by the great rivers of Asia Minor, and it was in this metal that the peoples of the Ionic seaboard first coined money, probably ca 750 B C Many of the cities of this part of the world have primitive coins of electrum, and in some places the use of the metal persists, although silver may also have become available The Cyzicene staters are much sought after by the collector, and it is surprising to find as many as 41 in the Weber Collection Many of these derive from famous collections of the last century, including those of Lord Ashburnham and Canon Greenwell Other electrum coins here represented are those of Phocæa, the small unidentified early coins of the cities of Ionia, the pretty one-sixth stater pieces of Lesbos, and two of the electrum staters which in recent years Prof P Gardner has identified as the coinage of the towns leagued together in the Ionian revolt against Persia at the end of the sixth century B C A later example of a presumed federal or alliance coinage is perhaps to be found in two examples at Ephesus of the very rare coins issued about 390 B C by Ephesus, Rhodes, Cnidus, Iasus and Samos These coins bear a common type, the infant Herakles strangling the two serpents, but if thereby an alliance is denoted no literary record of the event has survived Among other coins of outstanding interest are a unique tetradrachm of Smyrna of the fourth century B C well known from previous publications, a superb tetradrachm of Cnidus, two fine tetradrachms of Cos, and a very fine and rare stater of Amastris These coins are now all in the British Museum, the coin of Cnidus being a contribution from the National Arts Collection Fund Many of the cities weak to be sold by anyone The following shows that this cannot always be done with impunity A case heard at Bow-street in 1925 led Mr Graham Campbell to the decision that by usage of the trade the word "lysol" had come to mean a solution containing 50 per cent of cresols. Hence he must hold that a false trade description had been applied to the article, and that the article had been sold bearing such false trade description The defendant company was fined 15 guineas on each summons with 50 guineas costs, and the retailers were treated under the Probation of Offenders Act, only being required to pay 5 guineas costs It was then suggested by the defence that this action was an attempt by pharmacists to prevent the sale of lysol by grocers

What, it may be asked, is the proper scope of phenolic disinfectants? There is a definite surgical use for sterilising dental and general surgical instruments, cleansing areas to be treated, wounds, and sponges For this work lysol is specially convenient owing to its transparency In addition to metal instruments, rubber gloves and sheets, the walls and floors of operating rooms, and all sorts of things which have been or may have been in contact with patients suffering from infectious disease need actual sterilisation, as do stools, urine, and other emanations of such patients All these are well-defined medical and surgical requirements for which it is necessary to have a clear notion of the strength and general character of the disinfectant used. Where a patient is not treated at a hospital or clinic, much of the less critical work is necessarily left to the members of the household, who act under the general instructions of the doctor in charge of the case It is important, therefore, that if he orders a certain material to be used, the description should be sufficiently precise for him to know that it or its equivalent shall be obtained In addition to these definite uses many people seem to prefer disinfectants to absolute cleanliness, so masking a fetid smell with a phenolic one where the right thing would be to have no smell at all Public bodies are not exempt from blame in this matter, and although it may be argued that where it is impossible to secure cleanliness disinfection is the next best thing, yet it is difficult to see, in face of the known properties of phenol, that the sprinkling of a little carbolic powder or fluid on a garbage heap will do more than arrest decay on the surfaces actually touched by the disinfectant, whilst the bulk of the material may be fermenting and giving off foul gases and vapours

Some useful and suggestive work on the composition and properties of a variety of disinfectants, mostly phenolic in character, was published by the Medical and Health Department of Western Australia in 1924 In addition to pure carbolic acid, nine proprietary articles of the lysol group—cresol-soap solutions containing about 50 per cent of phenols, with one made from 50 per cent orthocresol and soft soap, four weaker lysol-like preparations, seven emulsified preparations, and four "phenyles" (emulsion-forming preparations of low phenol content, low cost and small bactericidal power)—were examined Tested against the same strain of colon bacillus in distilled water, the average coefficient of the 50 per cent lysol type was 2·4, of the weaker "lysols" from 0 2 to 1 6, varying with the proportion of cresol, whilst the emulsions averaged 8 4. The presence of only 3 per cent. of fæces, however, necessitated in all cases an increase in strength of the solutions for the same effect to be produced Whereas the proportion of carbolic acid had to be raised 1 4 times, the cresol soap solutions needed to be raised 2 4 times, and the emulsions about 8 2 times for the same effect to be produced These results show that for sterilising clean instruments, or inert things like rubber gloves, dilutions based on the coefficient may be used. But the presence of much organic matter of a kind which may form condensation products with phenols renders it necessary to use much stronger solutions than a consideration of the coefficient would suggest, and incidentally greatly decreases the value of the apparently more active emulsified liquids These facts make it all the more necessary that a medical man in advising as to the use of disinfectants should not only consider exactly what is appropriate, but should indicate that it *must* be obtained, making it clear that only pharmacists are allowed to sell preparations of the required activity

ADMINISTRATION OF VACCINATION

WE publish in this issue (p 271) an address by Dr James Bennett, delivered at the annual general meeting of the Association of Public Vaccinators on Jan 28th, on his retirement from presidency of the Association In this address he discusses impending changes in the administration of vaccination, dealing with its anomalous position under the Poor-law and the proposed transfer to the county and borough councils The pros and cons of this reform are fairly set out, and some of Dr Bennett's arguments are applicable to different but related problems which are likely to arise out of the Government's new Bill On the whole he considers that the proposed change would advance the cause of vaccination and improve the position of vaccinators It should also be welcome, he thinks, to the medical officers of the counties and boroughs, if only because it simplifies the machinery for general vaccination in the face of an epidemic Dr Bennett believes it to be very inadvisable, however, that vaccination should become the duty of assistant medical officers of health, pointing out that these officials often hold their posts for only a short time, and cannot get to know families and parents in the way that a public vaccinator should In the discussion which followed Dr Bennett's address there was almost unanimous agreement that the change of administration to counties and county boroughs would be in every way desirable, though some speakers expressed the opinion that it would be still more satisfactory to serve directly under the Ministry of Health There was a strong feeling that fixity of tenure and the question of superannuation should be kept prominently in view during discussions of the Government's Bill

REGIONAL DENTAL OFFICERS.

THE Ministry of Health announces the first appointment to the panel of dental surgeons who are to advise approved societies under the National Health Insurance Scheme in their annual allotment of over £2,000,000 for the provision of dental treatment as an additional benefit. This panel will enable the societies to obtain a second opinion as to the need for such treatment, to check estimates of cost received from dentists, and to standardise the materials supplied There are to be six full-time regional dental officers in England and Wales, who will be stationed at London (2), Birmingham, Manchester, Leeds and Cardiff The appointments just made are Mr H A Mahony (Principal Regional Dental Officer) and Mr Arthur Taylor in London, Mr J Woodford-Williams in Cardiff, Mr H G H Cowell and Mr T Dilks Page. One other appointment has yet to be made The cost of the service is to be met out of the funds of approved societies providing dental benefit under the new arrangements, which have been agreed upon between representatives of the societies and the dental profession.

THE FINGER-PRINTS OF IDENTICAL TWINS

A NOTE in our columns on Dec 25th, 1926 referred to an interesting paper by Dr G P Crowden published in the Guy's Hospital Reports the previous October and drawing attention to the remarkable similarity in physical make-up and mental development which characterised a pair of male twins who had come under detailed investigation Their size, depends on the recognition of the underlying nephritis. A constant specific gravity of the urine with high blood-urea and a diminished power of excreting dyes and urea are characteristic Albuminuria alone cannot be implicitly relied upon as a sign, and may be very slight Recently Dr F W Lathrop[2] has published a typical case of that type of renal dwarfism in which the deformity arises early in the second decade His paper is of special interest because of the very complete analysis of the blood which he records and the number of interesting biochemical problems raised in his commentary on the case In addition to severe acidosis and nitrogen-retention, phosphorus was present in the blood in roughly double its normal amount, whilst calcium was found in just over half its usual quantity, the deficiency being at the expense of the combined or un-ionised form. These changes are similar to those found in advanced renal inefficiency in adults, but it is suggested that when they occur in children before the epiphyses have united they cause failure of calcification at the epiphyses and consequently dwarfing and deformity This seems very probable It would be interesting to know whether the change in calcium and phosphorus values coincides with the onset of deformity The fact that in nearly every recorded case the deformity has been followed by death in less than two years suggests that it occurs only in the advanced stages of the disease when such changes in the calcium and phosphorus values would be present The absence of tetany in spite of such a deficiency of calcium is attributed to the fact that the normal amount of ionised calcium was maintained Dr Lathrop regards those cases in which deformity occurs in early childhood as an "allied condition." Probably there is no essential distinction, and the age of onset of deformity is determined by the rate of progress of the renal condition

THE MEDICAL SERVICE OF CHINESE ARMIES

Dr C M Oman, a captain in the Medical Corps of the U.S Navy, who has spent the last two and a half years in Pekin, has given his impressions of the medical service of Chinese armies in the *Military Surgeon* for January He writes from an experience of the treatment of 5000 military casualties There is, he says medical organisation of a sort, it was laid down for the Chinese Army in 1912, when the Pekin Army Medical College was established to provide trained medical officers Theoretical instruction has been given, but there seems to have been no dissection, no laboratory work, and little or no clinical work attached to it These officers are available to help the Chinese army, but there is no Chinese army at present There are many armies, numbering in all about 1¼ million, who billet themselves on the inhabitants They have no hygiene as we understand it, no purified water, no isolation for infectious diseases, no latrines, no anti-tetanic serum There is in China no tradition inculcating care of sick or wounded There are few trained surgeons, probably not 30 in all China, able to do abdominal work Dr Oman once found a force of 18,000 men with but one medical officer, and he with no effective orderlies or nurses, no instruments but his own, no operating room or X ray outfit, no prearranged transport for his wounded The Chinese have become accustomed to trusting to the humanity of foreign medical agencies for the care of their wounded Dr Oman tells of a battle near Tientsin in 1925, when the best Chinese army—that of Feng Yu Hsiang—left its wounded to find their way to Pekin, 70 miles away They began to arrive in a couple of days, and soon there were some 2000 to be cared for As no Chinese came forward the Pekin Union Medical College, foreign doctors and laymen, equipped and staffed a casualty hospital This situation repeated itself a few months later, and the Kuominchun army paid nothing for the help thus afforded But there is some evidence of a changing outlook The *World's Health* for November last tells of the spread of nursing education in China under the International Red Cross, and its almanac asserts that many wounded men have been cared for in the four Red Cross hospitals in Shanghai Shanghai is also the centre of an active health propaganda, of which Dr W W Peter's pictures are the most telling feature

POTENTIAL REDUCTION OF CANCER MORTALITY

To a recent meeting of the Section of Epidemiology of the Royal Society of Medicine, Prof Major Greenwood and Dr Janet Lane-Claypon contributed a paper on the possibility of reducing the present mortality from cancer of the breast and uterus The views advanced were based on results obtainable with present methods of treatment, and did not take into account any reduction already effected by operative procedures In the first place, Dr Greenwood and Dr Lane-Claypon took out the age-distribution of the registered deaths from cancer of the breast and uterus, and compared them with the age-distribution of hospital applicants for treatment who were suffering from these diseases The figures for the mortality-rates for this country at the different age-periods were taken from those prepared for and published by the League of Nations It was found that whereas 24 per cent of all deaths from cancer of the breast occurred among women over the age of 70, and 46 7 per cent over the age of 60, the percentages of applicants of those ages compared with the total number of patients were 2 8 and 17 6 respectively Hence, although the mortality-rates are high at the extreme of life, the number of applicants for treatment is small Similarly, although the mortality from cancer of the uterus in these two age-periods was 14 4 per cent and 37 8 per cent of the whole mortality from this disease, the numbers of hospital applicants of these ages were only 2 1 per cent and 17 1 per cent of the total numbers In order not to over-estimate the possibilities it was assumed that no reduction in mortality can be effected among women over the age of 70, a supposition which errs on the safe side Figures prepared in part from the literature and in part from data specially obtained from hospitals in this country, showed that youth does not offer any disability as to results of operation This being so, it may be assumed that all women under the age of 70 are equally capable of being treated successfully, and hence, theoretically, about 75 per cent of patients suffering from cancer of the breast and 85 6 per cent of those suffering from cancer of the uterus are capable of receiving such benefit as is offered by present treatments Dr Greenwood and Dr Lane-Claypon stated that not more than 50 per cent of all women dying of cancer of the breast can be found to have made any application for effective treatment—i e, treatment of a nature likely to secure permanent removal of the disease The corresponding figure for cancer of the uterus is not as yet available, but is believed to be rather worse The Leeds statistics already published show that if radical operation is undertaken at a stage of the disease when the growth is still confined to the breast, 80 per cent of the patients are alive ten years or more after operation After further analysis and comparison of the above data, Dr Greenwood and Dr Lane-Claypon concluded that a 50 per cent reduction in the mortality from cancer of the breast could be achieved with present methods if all women would attend for radical operation at an early stage of the disease Similar results could be obtained with cancer of the uterus At the present time, they state, the condition of little more than half of all the applicants for treatment is operable and in many of these the disease is in an advanced stage The present operative mortality-rate for all cases may be taken at about 17 3 per cent, and the survival-rate at 10 years at about 32 6 per cent of all cases operated If the patients were all in the early stage of the disease, the operative mortality would be reduced, and at the same time the survival-rate would where the coinage is less spectacular are well represented, and there are many varieties, new or not well-known, of the later imperial coinage of the Greek towns when under the rule of the Roman Emperors. It remains to add that Mr. Forrer has performed his pleasant task with the thoroughness and care which marked the earlier volumes.

---

DIAPHRAGMATIC HERNIA

HERNIA through the diaphragm was known as long ago as the days of Ambroise Paré. At the autopsy on an officer who died in great pain eight months after a bullet wound, Paré found a large distended loop of the colon in the thoracic cavity; the hole by which it had entered was, he tells us, too small to admit the little finger. For many decades, however, the condition remained a mere curiosity of the dissecting-table. Now and again a writer would describe it, and suggest such remedies as bandaging and blistering. Bowditch and Péan, in 1865 and 1880 respectively, justified operation as a last resort, but on the whole the condition received little attention until the late war, when the daily occurrence of cases similar to Paré's brought it into prominence and enabled it to be studied exhaustively. Moreover, the use of X-rays revealed a group of herniæ that were congenital and not traumatic at all, and a whole series that would never have been discovered, because of the absence of strangulation. Dr. Jean Quénu,[1] in a recent summary of the subject to which he contributes much first-hand information, gives an idea of the frequency of diaphragmatic hernia when he states that there are now over 1500 cases in the literature. He classifies it as congenital and traumatic. The congenital form is due to a failure of the two parts of the diaphragm to meet properly, and so nearly always occurs postero-laterally. It is much more common on the left side, probably because the liver protects the right cupola, whereas the stomach exerts heavy pressure on the left. Traumatic herniæ, which are always left-sided, are generally the result of stabbing or shooting wounds. Often the hernia is not immediate but takes place some time afterwards, when a blow or violent effort forces the weak barrier of the healed scar. Nevertheless, Dr. Quénu holds that many so-called secondary herniæ are really primary ones which have been neglected. A congenital hernia, he finds, nearly always involves the stomach, the transverse colon and the great omentum, and sometimes takes in parts of the small intestine, cæcum, liver, and pancreas. The organs are, as a rule, free from attachment to the thoracic cavity and are easy to withdraw, but sometimes, when an old traumatic hernia has coincided with a more or less septic hæmothorax, there are very intractable adhesions. The great omentum may form a false sac over the intruding mass. The true sac is very rare and is hardly ever seen except in "fœtal" herniæ—i.e., those developed later in the intra-uterine life than the congenital or embryonic herniæ. It is easy to realise that strangulation at the point of rupture may cause very severe lesions, such as perforation, with an escape of gastric or intestinal contents into the pleural cavity.

According to Dr. Quénu, the symptoms of a large hernia involving both stomach and colon are those of acute gastric, intestinal, or cardio-pulmonary disturbances, always accentuated by meals. Signs of displacement are sometimes fairly obvious and sometimes elusive; they vary in different patients, and in the same patient from time to time, and alter with changes of position or the presence of food in the alimentary tract. Radiography often makes diagnosis a simple matter, and the hernia can sometimes not only be seen but be accurately measured; some cases, however, simulate diverticulum of the œsophagus or an abnormally high cupola of the diaphragm. The former are generally exposed by watching the way in which the pocket fills and empties, and by the presence of the shadow of a normal stomach underneath. The latter may offer some difficulty, especially when the diaphragmatic condition is of the kind described by J.-L. Petit in 1780 as "eventration," when the diaphragm undergoes distension at one point and is pushed upwards into the pleura in the shape of a deep, narrow dome. When this has happened, the resulting photograph is practically identical with one of a hernia. Dr. Quénu recounts various ways of making the diaphragm cast a clearer shadow and reveal its position, and correctness of diagnosis is important in that, whereas hernia demands operation, eventration is generally better left alone.

The treatment varies according to whether the hernia is a traumatic or strangulated one requiring immediate operation, or one which can be dealt with at a chosen time. Dr. Quénu describes as the typical operation one which begins with an exploratory incision in an intercostal space, varying from the sixth to the tenth according to the site of the rupture. The aperture is prolonged through the abdominal wall to the middle line, opening all the soft parts and the peritoneum. An incision is then made through the costal cartilage and the diaphragm to the site of the hernia. Adhesions are freed and the ectopic organs withdrawn. The orifice is obliterated and the diaphragm sewn up at different points as far as the chondral attachments. In closing the thorax, the intrapleural air is exhausted with a syringe. The pneumothorax produced by the operation has never been known to have ill-effects, and the diaphragm heals extremely well. If much of its substance has to be removed, there are several ways of filling the gap. Different operators have used the stomach, a piece of omentum, the left lobe of the liver, a lung, or a graft of muscle from the abdominal wall. Dr. Quénu suggests that a free graft of aponeurosis might be the most satisfactory method, but it has not yet been tried. Operation for strangulated diaphragmatic hernia is an emergency, and the condition is very grave indeed, but the method described allows the patient the most reasonable chance of recovery.

RENAL DWARFISM

IT is mainly owing to Dr. H. Barber, who published[1] the first three cases of his remarkable series in 1913, that the rare condition known as renal dwarfism has been rescued from the limbo of "late rickets" and recognised as a separate entity. Its importance lies in the invariably fatal results that follow operative treatment of the deformities associated with it. The fundamental pathology consists of an extreme degree of chronic interstitial nephritis, unaccompanied by œdema, and with little or no cardiovascular hypertrophy. In the later stages calcification at the epiphyses becomes very deficient and deformity commonly follows. Great stunting of growth is a feature in all cases, and girls are affected rather more often than boys. The renal symptoms appear insidiously in early childhood with thirst and polyuria and may pass unrecognised by the parents, but gradually attacks of drowsiness, headache, and vomiting supervene, and death in uræmia occurs on the average about the twelfth year. Deformity is present in some 70 per cent. of cases and may come on before the symptoms of renal disease are noticed. The type varies with the age of onset. Before the age of nine it takes the form of slipping and displacement of the epiphysis on the diaphysis. The lesions are painless. They affect mainly the knees and wrists, but frequently the ankles and shoulders as well, and cause great disability. Radiographically the appearance is striking and distinctive. After the age of nine separation of epiphyses does not occur, and the deformities cannot be distinguished from those of so-called late rickets. Genu valgum is by far the most common deformity in this type of case. The diagnosis is usually easy if the condition is borne in mind, and

CCIX—TREATMENT OF UNUNITED FRACTURES

II SPECIAL FRACTURES

LAST week the general principles governing the treatment of ununited fractures were summarised, special stress being laid on recognition of the fact that the success of any method depends entirely on the production by the body of callus which is adequate in quantity and in density; failing this, no mechanical device will long resist severe external stress, such as the effects of gravity, or powerful muscle contractions

Each bone is apt to present certain special features which demand brief reference

The Humerus

(*a*) When the gap between the ends of an ununited fracture of the humerus is only a moderate one, it is best to shorten the arm by rawing the bone ends and cutting each in the form of a step so that they fit together

The contact can be maintained accurately for a time by drilling the ends and anchoring them together with strong catgut This prevents displacement during the application of a plaster-splint, such a splint is necessary, since even stout wire may cut its way through the bone and fail to keep the alignment correct long enough for callus to form The plaster should fix the elbow by including the forearm, and also the shoulder, and to do this comfortably it should take its bearing from the pelvis and lower ribs

If the upper fragment is short—i e, ending above the insertion of the deltoid—the arm should be put up in full abduction, but at lower levels any angle which is wide enough to permit comfortable application of the plaster is sufficient

(*b*) If the gap between the ends of the humerus is so great that an attempt to secure end-to-end union would shorten the arm unduly—e g, more than two inches—then it is best filled by a heavy graft from the crest of the tibia

As there is a great leverage on such a graft, once the plaster has been removed, it is usually best to apply it in the form of two parallel struts, one lying for about one inch or more on the surface of each fragment, which has been rawed to receive it, and the second wedged into the medullary cavity of each end This is one of the exceptions to the rule that intramedullary grafts are bad, for in this case the central graft is only expected to fulfil a mechanical function in steadying the fragments, while the inlay graft and the rawed cancellous bone produce callus The ultimate absorption of the central graft is thus immaterial Once the graft is driven into each medullary cavity a little coaxing being required to get it into the second end, it holds itself; the inlay graft needs fixing either by ligatures of strong catgut encircling the shaft, or by sutures through the periosteum.

Immediately after the operation a plaster support should be applied If it is well reinforced in the axilla it is possible later to cut a large lid out of the upper arm portion, and through the window so formed the stitches can be removed. while massage can be given to the limb and the muscles stimulated to contract in order to improve the nutrition of the graft without putting any strain upon it Later the forearm also can be freed and some voluntary movements of shoulder and elbow permitted before the full range is allowed An alternative to the plaster splint is the so-called 'aeroplane" one, made of light metal struts, taking their bearing on chest and pelvis, keeping the shoulder abducted, and allowing traction from the elbow

Radius

(*a*) Ununited fractures of the neck of the radius, in which the head is displaced, and there is disability in connexion with rotation of the forearm, or use of the elbow, are best treated by excision of the head through a small incision over its posterior aspect Care must be taken not to injure the posterior interosseus nerve in its course round the outer aspect of the bone, and not to leave any raw bone, which might produce spurs and so again interfere with joint movement No splint is necessary after operation

(*b*) An ununited fracture of the shaft of the radius is likely to be a very disabling condition, as the carpus works almost entirely on the radius

A short gap is best bridged, after each end has been rawed, by a thin sliver-graft, which is easily cut from the surface of the longer fragment by a wide gouge, for the bone is light and vascular, such a graft, attached by catgut ligatures to a rawed surface on each fragment, usually causes a rapid production of callus, in which the normal architecture of the bone is quickly reproduced

Where the gap is a long one such a light graft would be inadequate to stand the strain, and a heavy one from the front of the tibia should be used, applied similarly, and, as union at the areas of contact is rapid, although the part between may be very slow to become vascularised, it is likely to be sufficiently strong to stand the leverage of the hand until this occurs

When a long gap in the radius is associated with much destruction and fibrosis of the soft parts, a tibial graft would have very little chance of surviving, since the thin skin of the scarred area is likely to slough over it, therefore, in such a case, it is best to shorten the ulna so as to reduce the gap completely, or at least almost so This should be done at one session, the radius being rawed and, if necessary, grafted at a subsequent operation, after the ulna is again united and available as a splint to the other bone

Fractures of the shaft of the radius are best approached from the dorsum of the forearm on one side of the radial extensors of the carpus

Ulna

Ununited fractures of the ulna in its lower third may give no disability at all, in which case they should be left alone

In the upper third they are likely to be troublesome to manual workers from interference with the action of the triceps When such a fracture is explored it is usual to find the ends of the bone sclerosed and avascular for some distance, so that a light sliding graft is unlikely to result in union A tibial graft with wide attachment to each fragment should be tried, but even this may gradually atrophy and break at the level of the gap

It is not desirable to interfere with the radius, whose integrity is vital to the use of the hand

Carpal Scaphoid

A recent discussion of the British Orthopædic Association revealed considerable divergence of opinion as to the correct treatment of ununited fractures of the carpal scaphoid

Statistics showed that in many cases such a fracture caused no disability in a manual worker, while, curiously, others with an apparently identical injury were totally incapacitated from work The former group obviously needs no treatment, the latter is usually benefited by excision of the scaphoid There was a division of opinion among the surgeons as to whether it was sufficient to remove half the scaphoid or whether it was preferable to remove the whole bone and also the semilunar, so as to allow the os magnum to telescope back into the proximal carpal row The latter procedure has given very satisfactory results in the hands of those who have used it

Femur

Formerly subcapital fractures of the *neck of the femur* were expected to result in non-union but the pioneer work of Royal Whitman has demonstrated that this should be the exception, not the rule

Although in these fractures the isolated head of the femur is cut off from its main blood-supply, its capsular attachments yet if reduction is adequate, so that the neck comes into firm contact with the raw area on the head, then good union will occur in a majority of cases, even in the very old Such reduction can only be obtained under anæsthesia and it must be followed by adequate, prolonged fixation Whitman's own method is by a long plaster spica reaching from the thorax to the toes, with the hip in full abduction extension and some internal rotation. This allows frequent turning of the patient—e g, for an rise The improvement from these causes, it is believed, would be almost certainly not less than 17 3 per cent, so that the survival-rate would reach 50 per cent of all cases As 85 6 per cent of those who die at all ages from this trouble are capable of being operated on if they could be persuaded to attend early for treatment, it follows on this calculation that not less than 42 per cent reduction could be secured among those who at present die from cancer of the uterus Dr Greenwood and Dr Lane-Claypon pointed out that the data available for this country show that the mean period elapsing after the patient has become aware of her symptoms is from 8 to 12 months for cancer of the breast (according as the cases of long duration are or are not included) and from 6 to 9 months for cancer of the uterus Hence, although a small proportion of women may be unaware of their trouble until the disease has passed its early stages, it is at least certain that in both forms of cancer there is great unnecessary delay in making application for treatment The view that a reduction of approximately 50 per cent could be effected has been confirmed statistically by calculations based on the survivals among known cases In the course of the subsequent discussion, Sir James Berry and Mr W Sampson Handley strongly emphasised the supreme importance of early treatment

THE LAW AND TRADITION OF MEDICAL PRACTICE

MR W SANDERSON and Mr E B A Rayner, both barristers-at-law, have written an interesting introduction to a complete work[1] on the law and tradition of medical practice, the projected volume being "a treatise on the rights and duties of physicians, surgeons and dentists, with a complete description of the status of apothecaries and midwives" The work contemplated will thus cover an enormous field, while the introduction deals with little more than general principles, omitting, further, any mention of public health or forensic medicine, because, as is pointed out, both subjects, while extending over a wide field of law, are adequately dealt with in existing text books The authors' description of the contact of medicine and law—that is the relation of medicine to the body politic will make useful reading to every medical practitioner We are all supposed to know the law—that is to say, to be aware of the rules that govern this relationship, but while many other citizens can ascertain with fair facility where they stand in regard to particular enactments, in no class, except among lawyers themselves, is professional routine so perpetually in touch with various general and special regulations Our pages, under the head of "Medicine and the Law," testify to the wide range of questions which fall under this title, and not a little to the presence of anomalies in administration The statements in this small book upon tradition and custom, as those upon salaries and fees, contain much information that will enable the reader to understand sociological principles as applied to the conduct of medical practice, it is pleasing to find the arguments developed on which the views are founded that the law is still developing in the wake of medical tradition, and that "the striking harmony between medicine and the body politic has been produced by the high standards of honour and service continuously exhibited by the medical profession, and has been as continuously fostered by the law under the guidance of the judges" The warning against the thoughtless granting by medical men of press interviews is scathing, and we are not surprised to learn that the terms employed should have led to a protest from the Institute of Journalists, nor that the authors should have signified willingness to modify the offending passage That mischievous or troublesome results have followed upon press interviews granted by doctors cannot be denied, and the annals of the General Medical Council can be quoted in support of this statement, but the inclusive indictment of all press reporters cannot be justified by facts

---

[1] An Introduction to the Law and Tradition of Medical Practice By William Sanderson, M A., LL B, of the Inner Temple, and E B A Rayner B A, LL B, of Gray's Inn, Barrister-at-law London H K Lewis and Co, Ltd. 1926 Pp 77 *7s 6d*

THERE has been definite improvement in Sir Ernest Hodder-Williams's condition generally during the past week

THE death occurred on Jan 25th, at the age of 69, of Dr Thomas Robert Bradshaw, consulting physician to the Liverpool Royal Infirmary

SIR Berkeley Moynihan, President of the Royal College of Surgeons of England, will deliver the Hunterian Oration in the Theatre of the College on Monday, Feb 14th, at 4 P M Fellows and Members who wish to be present are asked to apply to the Secretary for cards of admission

WE publish in another column a letter from a small committee of friends and admirers of the late Sir Clifford Allbutt, who have decided to erect at Papworth two cottages with which his name will be associated, which are to be used for the accommodation of men disabled by tuberculosis The inmates will be selected from among those who are unable to support themselves and families, and the association of Sir Clifford Allbutt's name with such beneficent work is very fitting, for he was deeply interested in the work of the colony from its outset We are sure that many of our readers will welcome the opportunity of helping the good work, while testifying their appreciation of the career of a great leader, this they can do by sending donations to the fund directed to Mrs Marcus Dimsdale, Papworth Hall, Cambridge

MR J Hugh Jones, who died on Monday of influenzal pneumonia, was a benefactor of metropolitan hospitals, for it was owing to his imagination and enterprise that the scheme for providing wireless to every hospital bed was successfully realised The money, collected through the columns of the *Daily News*, exceeded £34,000, which was sufficient to equip 15,781 beds in 122 hospitals, leaving something over for Borstal schools and lighthouses At a crucial time in his early life—as he told the subscribers to the fund when accepting a presentation—he received kindness from a Manchester hospital, and formed a resolution that if ever he grew up he would endeavour to do something for hospitals to mark his gratitude Mr Jones was clear-sighted enough to look upon broadcasting as an ally and not as a menace to newspaper production

---

ROYAL SANITARY INSTITUTE —A Sessional Meeting is to be held at 90, Buckingham Palace-road, London, S W 1, on Tuesday, Feb 15th, at 5 30 P M when a discussion on Immunisation Against Diphtheria will be opened by Dr William Robertson, medical officer of health for Edinburgh The chair will be taken by Sir Arthur Newsholme

CONTAMINATION OF MILK —At a conference of 149 local authorities, held at Leeds on Jan 27th, to consider the requirements of the Milk and Dairies Order of 1926 Dr J R Kaye, medical officer of health for the West Riding, said "In 42 per cent of the examples of milk we recently took we found liquid manure If a farmer does not supply pure milk," he went on, "he is not an honest man and ought not to be a churchwarden If I were a coroner I should want an inquest on every child under 12 who died from intestinal trouble I should look to milk first for the cause of death, and if I found it there I think I could win the day against the producer before a court and a sensible jury We have been too soft-hearted in the past A great deal is being done by some producers, but why should not Grade A be the standard milk? There should be a defined standard, and we ought to get real help from the magistrates instead of tinkering fines that are no use whatever" more direct evidence as to its nature was furnished by the observation that, unlike the vitamin obtained from it, the provitamin forms an addition compound with digitonin. Although the product recovered from the digitonide of ordinary cholesterol, by fractional extraction with xylol, contains the provitamin in increased amount, the complete separation of the latter from cholesterol or other sterols by this method does not appear to be practicable

Heilbron, Kamm, and Morton[9] *have recently shown* that by fractional recrystallisation cholesterol can be separated into fractions of varying provitamin content as judged by the intensity of the ultra-violet absorption spectra. We were able to test biologically, at Prof Heilbron's wish, two fractions, one of which had been found by the optical test to be four times more absorptive than ordinary cholesterol, and our biological test confirmed the spectroscopic one We are further informed by Prof Windaus that he has found it possible, by fractional distillation of cholesterol in a high vacuum to produce a 9 to 10-fold increase in provitamin content as measured by the optical test

These observations afford significant information with regard to the nature of the provitamin We may conclude that it is destroyed by bromine and by oxidation, but that it possesses the properties of a sterol, in so far as it forms an addition product with digitonin, and can be distilled in a high vacuum.

Previous work of Windaus (unpublished) had shown that the highly unsaturated sterol, ergosterol, could not be recovered unchanged from its bromide It had already been observed by its discoverer, Tanret, that this sterol is extremely sensitive to light and air (oxidation), and this fact, together with its property of forming an insoluble digitonide, suggested a resemblance to the provitamin The *admixture* in cholesterol from all animal sources (brain eggs gallstones, &c) of a sterol with more than one double bond *seemed* likely, in view of the well-known occurrence in phytosterols from vegetable oils, seeds, &c , of other representatives of this class, containing several double bonds Further from the fact that ergosterol possesses three unsaturated linkages one would expect it to show a greater absorption in the ultra-violet region than cholesterol, which has only one double bond.

We therefore took up *again, at Prof* Windaus's suggestion, the study of ergosterol, which we had previously found, after irradiation, "to be highly protective even in doses of one milligram,' when comparing it under identical conditions with 5 mg doses of irradiated cholesterol on the same batch of rats [5]

In view *of the more recent* work on the absorption spectrum of cholesterol by Heilbron, Kamm, and Morton,[9] and by Pohl,[10] we compared the absorption spectrum of ergosterol with that of *a specimen* of ordinary cholesterol, and found that ergosterol exhibited a very pronounced absorption in the ultra-violet region, the characteristic band of absorption being like that of the cholesterol at 280 μμ, but of enormously greater intensity The intensity of the absorption was estimated to be 1500–2000 times as strong as that of brain-cholesterol As the result of the irradiation this absorption band disappears just as in the case of cholesterol, at the same time the product loses its property of being *precipitated* by digitonin If the provitamin were *ergosterol*, or an unsaturated sterol of similar constitution, the amount present in ordinary cholesterol would be of the order of 0 05 per cent , or 1 part in 2000, and irradiated ergosterol should in this case possess antirachitic activity in correspondingly small doses

These assumptions have been fully *confirmed* by biological tests on rats A daily dose of 4/1000 mg of irradiated ergosterol cured and prevented rickets in rats kept on a rachitic diet Tests with still smaller quantities not yet completed, indicate that the limit of activity will prove to be less than 1/1000 mg

Conclusion

These results seem to justify the conclusion that the naturally occurring parent substance of vitamin D if not ergosterol itself, is a highly unsaturated sterol of similar constitution

It should be added that although ergosterol was originally isolated by Tanret from ergot, and named accordingly, similar or identical sterols have been obtained from a wide range of the lower plants occurring, for example, abundantly in the fat extracted *from certain yeasts The ergosterol used in our own* experiments above quoted was actually prepared from ergot, whilst that used by Prof Windaus was obtained from yeast.

This work, which will be published in detail elsewhere, is the outcome of mutual suggestions made in the course of written and verbal communications between Prof Windaus and ourselves, and Prof *Windaus will publish shortly the same results* in Germany.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT)

Influenza

THE Board of Health has issued a memorandum to medical officers of health asking for information about the prevalence of influenza The League of Nations' Health Section *has asked for all available* returns but as the disease is not notifiable in Scotland no statistics can be furnished without a special inquiry The medical officers of the principal towns are therefore asked to supply information at weekly intervals, this information being collected at schools hospitals, clinics, and factories, and from health visitors and medical practitioners

From current medical talk, I gather that in most areas in Scotland, some form of influenza is, at present *pretty common In the first* and second quarter of last year there was a considerable Scottish epidemic of influenza, mainly in the west, and the number of deaths in the 16 principal towns rose as high as 330 in April, after being 100 in March, 35 in February and 40 in January It fell again to 7 in August, and even as recently as the third week of last December *the* deaths numbered only 9 In the four weeks ending Jan. 22nd, however, there have been 56 deaths and there is thus definite indication of a *recurrence Whether* the disease is genuine influenza or not, the rising mortality shows its seriousness The respiratory diseases in general also show an increase, and for the four weeks ending Jan 22nd, *the number of deaths* corresponded to an annual death-rate of 3 8, 4 2, 3 3, and 3 2 per 1000 The average figure for the corresponding four weeks last year was 2 9 During the same period 96 cases of acute influenzal pneumonia have been notified compared with 71 last year, and 1105 cases of acute primary pneumonia compared with 784 last year. There seems *therefore* to be a perceptible increase of prevalence, but there is no very clear indication of the widespread infection which usually marks the arrival of specific influenza If the current diseases are truly influenzal it is obvious that the germ varies considerably in virulence From the wind and rain storms of November and December and the exceptional gales of January, it may perhaps be inferred that there is at least in Scotland, little probability of a wide spread serious epidemic this year But the relation of the weather to influenza is *too* uncertain perhaps, to justify even this mild prophecy hour twice a day, so as to diminish the risk of bedsores, and also allows him to be got up in a chair at the end of the first week The long is preferable to the short spica, which, to be efficient, has to include both thighs, for these elderly patients are apt to be the subjects of chronic rheumatism, so that it is undesirable to fix the good hip, lest it should stiffen A useful alternative is the Balkan-frame with a series of pulleys and with traction both in the transverse and long axes of the limb

Non-union in fractures of the *shaft of the femur* is generally due to the interposition of muscle between the ends, and when this has been removed by operation and the ends rawed, further interference is usually unnecessary

Where an actual gap is present similar methods to those which have been described in connexion with fracture of the humerus are applicable, only it must be remembered that in the lower limb shortening is most undesirable

Patella

Transverse fractures of the patella commonly result in fibrous union, owing to the intervention of fringes of torn quadriceps tendon between the fragments The fibrous tissue is likely to stretch and leave the knee weak. so that open operation is indicated, unless the patient's general condition is very unfavourable

All that is necessary is to free the bone edges, raw them and then fix them together by strong catgut sutures through the quadriceps expansion Provided that the knee is splinted in extension until bony union is shown by X rays to have occurred, it is unnecessary to use wire to fix the fragments Massage can be given early if a plaster splint is bivalved, or a Thomas knee-splint used

Tibia and Fibula

As the *tibia* is splinted to a certain extent by the fibula, it is often sufficient in treating an ununited fracture in this bone to slide down a graft of moderate thickness from its upper fragment, a groove having been made on the front of the lower fragment to receive it

A number of ununited fractures of the *fibula* give no disability, the functional result depending partly on the extent to which the fragments are firmly anchored by scar tissue, and partly on the nearness of the fracture to the ankle If weight-bearing is interfered with the bone should be grafted, which is readily done by an inlay graft from the tibia on the same side

Large Gaps in Bone after Removal of Tumours and Cysts

Spontaneous fractures due to the presence of a tumour or a cyst must be treated by operation whenever possible, for though they sometimes unite again spontaneously, they are very apt to refracture in the future, possibly on more than one occasion

The first stage in treatment then is radical removal of the cyst or tumour In the case of secondary carcinoma in a bone operation is rarely indicated as the patient's general debility or the primary growth overshadow the local bone condition Even without operation quite a number of these case unite spontaneously when treated like any ordinary fracture Naturally they tend to refracture, or else some other bone gives way next time

The innocent tumours which are amenable to removal usually leave a large deficiency in the bone, or at best an egg-shell cavity, which will not stand normal strains, so that a grafting operation is necessary Such a cavity can be filled with chip grafts from some vascular bone like the iliac crest Such chips are not good when surrounded by soft parts, as they are apt to become embedded in a mass of fibrous tissue, which does not make the shaft of a bone firm, but they do well when implanted in a rigid cavity If no shell remains after removal of the tumour, then one or more heavy grafts must be used to bridge the gap

It has been impossible here to give more than the merest outline sketch of such a complex subject as the treatment of ununited fractures

Special Articles.

ON THE NATURE OF THE PARENT SUBSTANCE OF VITAMIN D.

By O. Rosenheim and T A Webster
(From the National Institute for Medical Research, London)

In The Lancet of May 16th, 1925, we gave a short account of work we had carried out showing that cholesterol, having the characteristics then known of the " chemically pure " substance, was rendered antirachitic by exposure to ultra-violet light[1] This fact was also discovered independently and at about the same time by the American observers Steenbock and Black,[2] and Hess, Weinstock, and Helman[3]

Although this discovery has since been confirmed and accepted by numerous investigators in many countries, and has found practical application for the cure of rickets in children, we were able to show recently[4] that cholesterol when purified still further by a chemical method had lost the property of becoming antirachitic by irradiation

Further Work on Cholesterol Derivatives

The considerations which led us to this result were the outcome of work undertaken for the purpose of isolating the active substance and of determining the nature of the molecular groupings essential for the successful activation of cholesterol[5] We succeeded in obtaining from irradiated cholesterol, by the use of digitonin, a substance which was intensely active, but were unable to convert more than about 1/10 per cent of the cholesterol into this active substance The investigation of a series of suitably selected derivatives of cholesterol led us to the conclusion that, unless both the unsaturated linkage and the hydroxyl group of the cholesterol molecule were intact, the substance could not be activated In this part of the investigation the fact that the esters of cholesterol could be rendered antirachitic presented a difficulty in accepting the above conclusion unreservedly

In continuation of this work, carried out partly in collaboration with Prof Windaus (Gottingen) and published elsewhere,[6] we were able to offer a solution for these difficulties, and to prove conclusively that cholesterol purified by way of the dibromide cannot be activated by ultra-violet light, and no longer possesses the absorption spectrum in the ultra-violet region which had been considered characteristic for cholesterol[7, 8]

These facts threw new light on the photo-chemical formation of vitamin D It became evident that the precursor of vitamin D is not cholesterol itself, but a substance associated with cholesterol as obtained from all natural sources We have since extended these observations to the phytosterols, and have found that when these are purified by way of the bromides they also yield no vitamin to irradiation, whereas all vegetable oils, and the sterols obtained therefrom and not so purified, readily acquire antirachitic properties under the action of ultra-violet rays

These observations suggest that the provitamin (we propose to use this convenient term, suggested by Prof Windaus, for the parent substance of vitamin D) is destroyed by bromine, and we have further found that it is equally destroyed by oxidation—e g, by treating an acetone solution of cholesterol with potassium permanganate Treatment with blood charcoal also frees ordinary cholesterol from the provitamin, but whether this is due to oxidation or adsorption has not yet been established

Whilst these results afforded no means for the isolation or even concentration of the provitamin, naturales. The lowest part of the ileum was severed transversely, the rectum was thoroughly mobilised and cut transversely some 5 cm. above the anus, and the proximal end of the ileum was pulled through the rectum and fixed outside on the anus. At a second operation five months later the entire colon—ascending, transverse, and descending—was extirpated, together with the peripheral part of the ileum, and at the same time the artificial anus was closed by a plastic operation. The patient made an excellent recovery after both operations. The lowest part of the ileum, which had been pulled through the rectum sloughed away, so that the patient now possessed a few centimetres of his former colonic intestinal canal—viz., the lowest part of the rectum. His motions were at first very frequent, watery, and copious. Now they have regained the normal consistency; they are passed 6–8 times in 24 hours, and the sphincter is completely continent and acting normally. The extirpated colon was demonstrated. It is completely obliterated and very much shrunken, its walls are stiffened, and the lumen is filled with scar tissue. Up till now no case has been recorded in which such an extensive removal has been successful.

Another Method of Rejuvenation

For the last 18 months Dr. Doppler has been experimenting on suitable cases with the effects of painting the spermatic (or ovarian) artery with a 7 per cent. aqueous solution of carbolic acid. He has found that this produces marked hyperæmia of the testicle (or ovary) with enlargement of the gland. In cases in which there has been hypofunction the secretion of the hormones is decidedly increased and Dr. Doppler notes a remarkable improvement of appetite some 10 to 14 days after the painting. The nervous symptoms, he says, soon improve; the appearance of the individual becomes better, and the basal metabolic rate, which is generally lowered in hypofunction of the sexual glands, returns to normal. The physical and psychic activity of the patient is markedly increased. Dr. Doppler recently showed a series of patients (he has so far operated on 160) in whom the changes thus produced are very obvious. He explained that his method is much simpler than vasectomy or vasoligature and though it is useless in cases of psychic impotence it should be tried for organic impotence before other and more drastic measures.

MEDICINE AND THE LAW

Operation without Patient's Consent

To what extent is a surgeon justified in performing an operation to which the patient has not consented? This was the issue in a recent action at the Liverpool Assizes, a case reported in some detail in our news columns. The verdict went in favour of the defendant surgeon who maintained that he had operated to save life. The jury added a rider to the effect that operations should not be performed without the patient's consent—a general proposition to which all will assent. The legal position has two aspects, the civil and the criminal. Prima facie the performance of a serious surgical operation means the infliction of bodily harm, but it is saved from being a crime because of the patient's actual or tacit consent. Stephen's "Digest of the Criminal Law" has stated in the past very sensibly that any person may for surgical purposes connected with the preservation of life or health consent to the infliction of any bodily injury upon himself or on any child to whom he stands *in loco parentis* and who is too young to exercise reasonable discretion. The injury inflicted must be reasonably within the limits of the consent given; its risks must be explained or understood; and the operation must be performed with proper care or skill; otherwise the surgeon will be civilly or criminally liable. In the recent edition of 1926 the Digest states that if a person is incapable of giving consent it is not a crime to operate and inflict bodily harm without his consent and in spite of his resistance. Three illustrations of this proposition are given. In the first, if A is rendered insensible by an accident which makes it necessary to amputate one of his limbs before he recovers his senses, the amputation without his consent is not an offence. Secondly, if the accident makes him mad, the amputation, in spite of his resistance, is no offence. Thirdly, if B is drowning and insensible and A, to save his life, pulls B out of the water with a hook which injures him, this again is no offence. Against this passage the learned editors of the Digest retain the following footnote: "I know of no authority for these propositions but I apprehend they require none; the existence of surgery as a profession assumes their truth."

The Digest was primarily concerned with the criminal aspect; Stephen was explaining how far consent could be a defence to a prosecution for inflicting grievous bodily harm. The civil aspect of the matter—namely, the possible remedy of the patient in the form of obtaining damages where an operation has been performed without his or her consent—was dealt with in the case of Beatty v. Cullingworth, tried by Mr. Justice Hawkins in 1896, not mentioned in the law reports but noted in the Medico-Legal Society's *Transactions* in 1909 and cited in Halsbury's "Laws of England." It was the case of an operation for ovarian cyst. The patient told the surgeon beforehand that she would not consent to the removal of both ovaries as she was going to be married. "If you find both ovaries diseased," she said, "you must remove neither." The surgeon replied, "You may be sure I shall not remove anything I can help." When operating the surgeon found the right ovary cystic and removed it. He also found the left ovary to be in an early stage of the same process and he formed the opinion that it was necessary to remove it in order to save the patient's life. He did remove it and the patient afterwards brought an action for negligence. Hawkins addressed the jury as follows: "If a medical man with a desire to do his best for the patient, undertakes an operation, I should think it is a humane thing for him to do everything in his power to remove the mischief, provided that he has no definite instruction not to operate. There was here no question as to the propriety of the operation and the defendant always told the plaintiff she must give him a free hand. If you think tacit consent was given you must find for the defendant." The jury did so. It was, of course, a question of fact for the jury whether there was an express or tacit consent. The patient's previous stipulation quoted above is not quite consonant with the judge's statement that she had given the surgeon a free hand. Sir Frederick Pollock in a well-known text-book remarks guardedly that, "in cases of necessity when an operation is necessary and the patient is unconscious and unable to consent, and no person entitled to consent on his behalf is available the operation is probably justified."

Accident with a Junker Inhaler

An apprentice artificer, aged 16, died 20 hours after undergoing a minor operation for the removal of tonsils at the Royal Herbert Hospital at Woolwich. The evidence at the inquest at Lewisham showed that chloroform and ether had been administered by the open method. When one tonsil had been removed it was necessary to use the Junker apparatus, applying the anæsthetic through a nostril. In the assembling of the apparatus an error was made and the patient actually received liquid chloroform in the nostril instead of chloroform vapour. The mistake was at once discovered and all possible remedial measures were taken. The patient revived but subsequently died as stated. Witnesses gave evidence that the apparatus was assembled by a corporal in the laboratory. The corporal was not called at the inquest, and the two officers of the R.A.M.C. who had acted as anæsthetist and surgeon respectively stated that they did not desire to shift their responsibility. The coroner returned a verdict of "Accidental Death," expressing the hope that extreme care would

Blood Pressure from the Clinical Standpoint

At the last meeting of the Edinburgh Medico-Chirurgical Society there was a good discussion on blood-pressure, principally from the standpoint of the general practitioner Dr Porter gave a careful description of cases and the results of treatment, but on almost every essential question of theory and practice opinion was very much divided The points on which it turned were (*a*) the value of the diastolic pressure as an index and (*b*) whether in certain cases of high pressure any treatment was of any value The discussion, indeed, showed clearly Dr. Maitland Ramsay's wisdom in having arranged a course on the subject at St Andrews, in which Prof MacWilliam gave an admirable statement of the physiological position For the peace of mind both of patients and doctors, it is time to have the status of our present knowledge set out plainly, and it is to be hoped that the St Andrews course will be made available in a convenient form The subject is growing in importance, and methods of estimating blood pressure are now so simple and reliable that they can be used in general practice almost as a routine

New Children's Hospital at Leith

On Jan 29th Sir John Gilmour, Bt, Secretary of State for Scotland, opened the new Children's Hospital at Leith which has been erected as a memorial to the dead of the Leith Territorial Regiment, the 7th Royal Scots The earlier part of the present building was built over 60 years ago by the late Mr Simpson, architect to the former Leith Corporation The later section was built by his son, George Simpson,, who succeeded his father as corporation architect and built the fine hospital at East Pilton for infectious diseases, probably the best of its size at that date Mr Simpson has now added to his reputation by this third hospital He has made a fine use of the site, and the area round the hospital is unrecognisable by those who knew this part of Leith when it was covered by disgraceful slums The hospital itself is only large enough for some 50 beds, but it has also a first class out-patient department The two operating theatres would be hard to surpass for lighting and convenience, the fittings and furnishings are in the latest style, and the wards are commodious and luxuriously fitted This is a War memorial of the best type

Temporary Sterilisation by Means of Hormones

UNUSUAL interest has been aroused by the announcement of Prof. Ludwig Haberlandt, of the University of Innsbruck, that he has succeeded in rendering white mice and rats temporarily sterile by the injection of extracts prepared from the placenta and ovaries of pregnant mice He claims that later he was able to secure sterility in these animals for a period of six or seven weeks by feeding them on such extracts Prof Haberlandt based his experiments on the fact that the formation and expulsion of ova ceases during pregnancy He explained this
by saying that the endocrine secretion of an ovary
that operation is
be filled with chip grafts from roduces the symptoms of

administration is not entirely proved Prof Haberlandt points out that it is not yet possible to employ this method for the production of sterility in human beings. Use of the extracts is not without danger and there is a risk that permanent sterility may result instead of the temporary immunity to pregnancy desired. It will be remembered that Prof Haberlandt recently described experiments demonstrating the existence of a cardiac hormone [1]

The Health of Vienna

The pandemic of influenza now raging in Western and Northern Europe seems to have so far kept away from Austria There has been a slight increase in febrile bronchitis and gastro-intestinal troubles, and colds with aural and nasal complications have been very common, especially in children But the well-known "flu" of 1918–19, with its severe course and high mortality, is luckily absent as yet This is emphasised in the report of the Vienna "Health Bureau," presented a few days ago to the Municipal Senate, which gives some interesting figures for 1926 During that year the population of Vienna stood at 1,800,670, as against 2,020,090 in 1913 The number of live births was 23,485 last year, and 26,216 persons died The birth-rate is steadily falling and its decline is only partly counter-balanced by a decrease in infant mortality In 1910 no less than 17 5 per cent of all new-born children died in their first year, in 1914 the figure stood at 14 8 per cent, but last year, as in 1925, a mortality of only 8 per cent was recorded The number of persons certified as insane was 2356, and 40 per cent of the cases were described as due to alcohol, whereas in the previous year less than 35 per cent of insanity was attributed to this cause The campaign against tuberculosis has been actively carried on by the municipal board of health at its tuberculosis centres In 1924 25,113 persons applied to these institutions for examination and advice, but in 1925 the number went up to 43,720, and last year 65,217 were examined As every case found affected remains on record and all members of the family are looked after and cared for from the point of view of prophylaxis, this means a thorough examination of at least 20,000 families yearly Great care is taken of the health of children, and in the age-period of 3–6 years (pre-school age) all poor children may be sent to one of the public kindergartens, of which there are now 250 Here they are under constant supervision by trained nurses Great attention is also paid to the dental health of school-children School dental clinics were started in Vienna six years ago, and in 120 public elementary schools all the children between the ages of 6 and 14 now have their teeth looked after The poor ones are also treated free of charge, some 40,000 being thus under constant observation One remarkable feature of the returns is the comparatively large number of octogenarians In 1910 only 4 per cent of all deaths occurred in persons over 79 years, but last year the figure was 7 8 per cent In 1926, moreover, the general death-rate was only 14 per 1000, as against 19 per 1000 in 1910, and it is evident that more people live to a great age than formerly

Removal of the Entire Colon

A unique case was demonstrated recently at a meeting of the Vienna Society of Practitioners by Dr Eichenwald The patient was a man 26 years old, who had been under treatment for ulcerative colitis since 1914 In that year an artificial anus had been made in the cæcal region, and gradually the ulceration had healed with lavage of the colon But the lumen of the colon became progressively narrower until complete occlusion occurred, and rectal examination showed that beyond a point a few centimetres above the sphincter the walls of the canal had completely grown together In the spring of last year Dr Eichenwald resolved to perform an ileo-anastomosis so as to enable the patient, who had wonderfully regained his strength, to pass his motions per vias naturales The lowest part of the ileum was severed transversely, the rectum was thoroughly mobilised and cut transversely some 5 cm above the anus, and the proximal end of the ileum was pulled through the rectum and fixed outside on the anus At a second operation five months later the entire colon—ascending, transverse, and descending—was extirpated, together with the peripheral part of the ileum, and at the same time the artificial anus was closed by a plastic operation The patient made an excellent recovery after both operations The lowest part of the ileum, which had been pulled through the rectum, sloughed away, so that the patient now possessed a few centimetres of his former colonic *intestinal canal—viz, the lowest part of the rectum* His motions were at first very frequent, watery, and copious Now they have regained the normal consistency, they are passed 6–8 times in 24 hours, and the sphincter is completely continent and acting normally The extirpated colon was demonstrated It is completely obliterated and very much shrunken, its walls are stiffened, and the lumen is filled with scar tissue Up till now no case has been recorded in which such an extensive removal has been successful

Another Method of Rejuvenation

For the last 18 months Dr Doppler has been experimenting on suitable cases with the effects of painting *the spermatic (or ovarian)* artery with a 7 per cent aqueous solution of carbolic acid He has found that this produces marked hyperæmia of the testicle (or ovary), with enlargement of the gland In cases in which there has been hypofunction the secretion of the hormones is decidedly increased, and Dr Doppler notes a remarkable improvement of appetite some 10 to 14 days after the painting The nervous symptoms, he says, soon improve, the appearance of the individual becomes better, and the basal metabolic rate, which is generally lowered in hypofunction of the sexual glands, returns to normal The physical and psychic activity of the patient is markedly increased Dr Doppler recently showed a series of patients (he has so *far operated on 160*) in whom the changes thus produced are very obvious He explained that his method is much simpler *than* vasectomy or vasoligature, and though it is useless in cases of psychic impotence it should be tried for organic impotence before other and more drastic measures

MEDICINE AND THE LAW

Operation without Patient's Consent

To what extent is a surgeon justified in *performing* an operation to which the patient has not consented? This was the issue in a recent action at *the Liverpool* Assizes a case reported in some detail in our news columns The verdict went in favour of the defendant surgeon, who maintained that he had operated to save life The jury added a rider to the effect that operations should *not* be performed without the patient's consent—a general proposition to which all will assent The legal position has *two aspects*, the civil and the criminal Prima facie the performance of a serious surgical operation means the infliction of bodily harm but it is saved from being a crime because of the patient's actual or tacit consent Stephen's "Digest of the Criminal Law" has stated in the past very sensibly, that any person may, for surgical purposes connected with the preservation of *life or health* consent to the infliction of any bodily injury upon himself or on any child to whom he stands *in loco parentis and who is* too young to exercise reasonable discretion The injury inflicted must be reasonably within the limits of the *consent given*; its risks must be explained or understood and the operation must be performed with proper care or skill otherwise the surgeon will be civilly or criminally liable In the recent edition of 1926 the Digest states that if a person is incapable of giving consent it is not a crime to operate and inflict bodily harm without his consent, and in spite of his resistance. Three illustrations of this proposition are given In the first, if A is rendered insensible by an accident which makes it necessary to amputate one of his limbs before he recovers his senses, the amputation without his consent is not an offence Secondly, if the accident makes him mad, the amputation, in spite of his resistance, is no offence Thirdly, if B is drowning and insensible, and A, to save his life, pulls B out of the water with a hook which injures him, this again is no offence Against this passage the learned editors of the Digest retain the following footnote "I know *of no authority for these propositions* but I apprehend they require none the existence of *surgery as a profession assumes* their truth"

The Digest was primarily concerned with the criminal aspect, Stephen was explaining how far consent could be a defence to a prosecution for inflicting grievous bodily harm The civil aspect of the matter—namely, the possible remedy of the patient in the form of obtaining damages where an operation has been performed without his or her consent—was dealt with in the case of Beatty *v* Cullingworth, tried by Mr Justice Hawkins in 1896, not mentioned in the law reports, but noted in the Medico-Legal Society's *Transactions* in 1909, and cited in Halsbury's "Laws of England" It was the case of an operation for ovarian cyst The patient told the surgeon beforehand that she would not consent to the removal of both ovaries as she was going to be married "If you find both ovaries diseased," she said, "you must remove neither" The surgeon replied, "You may be sure I shall not remove anything I can help" When operating, the surgeon found the right ovary cystic and removed it He also found the left ovary to be in an early stage of the same process, and he formed the opinion that it was necessary to remove it in order to save the patient's life He did remove it, and the patient afterwards brought an action for negligence. Hawkins addressed the jury as follows "If a medical man, with a desire to do his best for the patient, undertakes an operation I should think it is a humane thing for him to do everything in his power to remove the mischief provided that he has no definite instruction not to operate There was here no question as to the propriety of the operation and the defendant always told the plaintiff she must give him a free hand If you think tacit consent was given, you must find for the defendant" The jury did so It was, of course, a question of fact for the jury whether there was an express or tacit consent The patient's previous stipulation, quoted above, is not quite consonant with the judge's statement that she had given the surgeon a free hand Sir Frederick Pollock, in a well-known text-book, remarks guardedly that, "in cases of necessity when an operation is necessary and the patient is unconscious and unable to consent, and no person entitled to consent on his behalf is available, the operation is probably justified"

Accident with a Junker Inhaler

An apprentice artificer aged 16, died 20 hours after undergoing a minor operation for the removal of tonsils at the Royal Herbert Hospital at Woolwich. The evidence at the inquest at Lewisham showed that chloroform *and* ether had been administered by the open *method* When one tonsil had been removed, it was necessary to use the Junker apparatus, applying *the anæsthetic* through a nostril In the assembling of the apparatus an error was made, and the patient *actually received* liquid chloroform in the nostril instead of chloroform vapour. The *mistake* was at once discovered *and all possible* remediary measures were taken The patient revived but subsequently died as stated Witnesses gave *evidence that* the apparatus was assembled by a corporal in the laboratory The corporal was not called at the inquest, and the two officers of the R A M C who had acted as anæsthetist and surgeon respectively, stated that they did not desire to shift their responsibility. The coroner returned a verdict of "Accidental Death" expressing the hope that extreme care would

Blood Pressure from the Clinical Standpoint.

At the last meeting of the Edinburgh Medico-Chirurgical Society there was a good discussion on blood-pressure, principally from the standpoint of the general practitioner Dr. Porter gave a careful description of cases and the results of treatment, but on almost every essential question of theory and practice opinion was very much divided The points on which it turned were (*a*) the value of the diastolic pressure as an index and (*b*) whether in certain cases of high pressure any treatment was of any value The discussion, indeed, showed clearly Dr. Maitland Ramsay's wisdom in having arranged a course on the subject at St Andrews, in which Prof MacWilliam gave an admirable statement of the physiological position For the peace of mind both of patients and doctors, it is time to have the status of our present knowledge set out plainly, and it is to be hoped that the St Andrews course will be made available in a convenient form The subject is growing in importance, and methods of estimating blood pressure are now so simple and reliable that they can be used in general practice almost as a routine

New Children's Hospital at Leith

On Jan 29th Sir John Gilmour, Bt, Secretary of State for Scotland, opened the new Children's Hospital at Leith which has been erected as a memorial to the dead of the Leith Territorial Regiment, the 7th Royal Scots The earlier part of the present building was built over 60 years ago by the late Mr Simpson, architect to the former Leith Corporation The later section was built by his son, George Simpson,, who succeeded his father as corporation architect and built the fine hospital at East Pilton for infectious diseases, probably the best of its size at that date Mr Simpson has now added to his reputation by this third hospital. He has made a fine use of the site, and the area round the hospital is unrecognisable by those who knew this part of Leith when it was covered by disgraceful slums The hospital itself is only large enough for some 50 beds, but it has also a first class out-patient department The two operating theatres would be hard to surpass for lighting and convenience, the fittings and furnishings are in the latest style, and the wards are commodious and luxuriously fitted This is a War memorial of the best type

Temporary Sterilisation by Means of Hormones

UNUSUAL interest has been aroused by the announcement of Prof Ludwig Haberlandt, of the University of Innsbruck, that he has succeeded in rendering white mice and rats temporarily sterile by the injection of extracts prepared from the placenta and ovaries of pregnant mice He claims that later he was able to secure sterility in these animals for a period of six or seven weeks by feeding them on such extracts Prof. Haberlandt based his experiments on the fact that the formation and expulsion of ova ceases during pregnancy. He explained this by saying that the endocrine secretion of an ovary …nduces the symptoms of … the formation of ova … the responsible agent … a pregnant animal into … t was found that the … sed ovulation in the … within the last three … pregnant ovary and …) with … d that … led to … after … e not … oral administration is not entirely proved Prof Haberlandt points out that it is not yet possible to employ this method for the production of sterility in human beings Use of the extracts is not without danger and there is a risk that permanent sterility may result instead of the temporary immunity to pregnancy desired It will be remembered that Prof Haberlandt recently described experiments demonstrating the existence of a cardiac hormone [1]

The Health of Vienna

The pandemic of influenza now raging in Western and Northern Europe seems to have so far kept away from Austria There has been a slight increase in febrile bronchitis and gastro-intestinal troubles, and colds with aural and nasal complications have been very common, especially in children But the well-known "flu" of 1918–19, with its severe course and high mortality, is luckily absent as yet This is emphasised in the report of the Vienna "Health Bureau," presented a few days ago to the Municipal Senate, which gives some interesting figures for 1926 During that year the population of Vienna stood at 1,800,670, as against 2,020,090 in 1913 The number of live births was 23,485 last year, and 26,216 persons died The birth-rate is steadily falling and its decline is only partly counter-balanced by a decrease in infant mortality In 1910 no less than 17 5 per cent of all new-born children died in their first year, in 1914 the figure stood at 14 8 per cent, but last year, as in 1925, a mortality of only 8 per cent was recorded The number of persons certified as insane was 2356, and 40 per cent of the cases were described as due to alcohol, whereas in the previous year less than 35 per cent of insanity was attributed to this cause The campaign against tuberculosis has been actively carried on by the municipal board of health at its tuberculosis centres In 1924 25,113 persons applied to these institutions for examination and advice, but in 1925 the number went up to 43,720, and last year 65,217 were examined As every case found affected remains on record and all members of the family are looked after and cared for from the point of view of prophylaxis, this means a thorough examination of at least 20,000 families yearly. Great care is taken of the health of children, and in the age-period of 3–6 years (pre-school age) all poor children may be sent to one of the public kindergartens, of which there are now 250 Here they are under constant supervision by trained nurses Great attention is also paid to the dental health of school-children. School dental clinics were started in Vienna six years ago, and in 120 public elementary schools all the children between the ages of 6 and 14 now have their teeth looked after The poor ones are also treated free of charge, some 40,000 being thus under constant observation One remarkable feature of the returns is the comparatively large number of octogenarians In 1910 only 4 per cent of all deaths occurred in persons over 79 years, but last year the figure was 7 8 per cent In 1926, moreover, the general death-rate was only 14 per 1000, as against 19 per 1000 in 1910, and it is evident that more people live to a great age than formerly

Removal of the Entire Colon

A unique case was demonstrated recently at a meeting of the Vienna Society of Practitioners by Dr Eichenwald. The patient was a man 26 years old, who had been under treatment for ulcerative colitis since 1914 In that year an artificial anus had been made in the cæcal region, and gradually the ulceration had healed with lavage of the colon But the lumen of the colon became progressively narrower until complete occlusion occurred, and rectal examination showed that beyond a point a few centimetres above the sphincter the walls of the canal had completely grown together. In the spring of last year Dr Eichenwald resolved to perform an ileo-anastomosis so as to enable the patient, who had wonderfully regained his strength, to pass his motions per vias

THE PAPWORTH COLONY AND SIR CLIFFORD ALLBUTT

To the Editor of THE LANCET

SIR,—A small committee of the friends and admirers of the late Prof Sir Clifford Allbutt has decided to erect to his memory at Papworth two cottages with which his name will be permanently associated, for men disabled by tuberculosis The men will be chosen from among those who could not under ordinary conditions support themselves and their families Sir Clifford Allbutt as President of Papworth Colony from the beginning was always deeply interested in the work there, and it is felt that there could be for him no more fitting memorial

A certain amount of money has already been promised, and we shall be very grateful if those who would like their names added to this memorial to a great man will kindly send donations, however small, to Mrs Marcus Dimsdale Papworth Hall Cambridge It is hoped that the cottages will be opened some time during the summer by H R H the Prince of Wales, and that as many subscribers as possible will endeavour to be present

We are, Sir, yours faithfully,
FREDERICK MILNER
HUMPHRY ROLLESTON
ARCHIBALD E GARROD

Papworth Hall, Cambridge, Jan. 30th, 1927.

ASYMMETRY OF THE JAWS

To the Editor of THE LANCET

SIR,—Hitherto I have been unable to find in any of the ordinary text-books of medicine or surgery reference to simple arthritic or synovitic conditions affecting the temporomandibular joint It does not appear to be commonly affected by the diseases which cause so much trouble in other joints of the body—perhaps fortunately so, since it is constantly and necessarily used in biting mastication and articulation My attention has been drawn to this subject by virtue of a recent personal attack of acute inflammation of the temporomandibular joint of the right side The attack was unlike anything previously experienced and though acutely painful for a time, seemed not to be serious for it cleared up entirely in three or four days with external application of ung methyl salicyl co (B P C) For reasons which follow, however, I have thought the condition would bear description

In the first place, as with so many similar affections, no likely causal factor was apparent The attack commenced with an initial grating sensation experienced only on opening the mouth very widely, more particularly when lowering the jaw was combined with protraction The affection remained in this simple state for about a fortnight without appearing to get either worse or better At the end of this time the condition suddenly became more acute and the inflammation more extensive The grating sensation was now felt during the ordinary movements of the joint being, of course, much more marked during the movements already alluded to In addition to the grating there was now a fair degree of pain such that the mouth was unable to be fully opened without a sense of impending dislocation accompanied by considerable pain. The grating, too, was of a peculiar type being *heard* rather than felt It seemed as if the mandibular condyle were endeavouring to slip-over a roughened *eminentia articularis* This was especially so during attempts at protraction of the jaw. After a few days of treatment the inflammation subsided and has left no damage as far as sensations enable one to judge

To me the condition has been most interesting on account of its unilateral position The question naturally arises as to why the process should affect the joint of one side only Probably the simplest cause would be a draught or some similar influence playing on the affected side This explanation seems feeble and insufficient to account for all the facts, especially considering the rather subacute commencement of the process, which is *certainly not* suggestive of cold or exposure such as is productive of one form of facial nerve paralysis It rather seems to me that the explanation is to be sought for in the anatomical asymmetry of the temporomandibular joint Most likely the side affected is the joint used more than its fellow and hence open to more damage In support of this is the fact that during the attack the mandibular condyle could be felt to make a greater excursion on the affected than on the normal side. When both joints are normal the excursion of the condyles is not appreciated, the movement of joint surfaces being an action that is not brought into consciousness except in a vague or general way. In the inflamed state the movement is only too well appreciated

My inference is that probably the articular surfaces of the right temporomandibular joint are more extensive than the left, possibly from greater usage in mastication or as a heritable quality, In brief, is it not possible that man is right-jawed as well as right-handed ?

The anthropologists do not seem to have paid much attention to measurements of the condyles of the jaw Asymmetry is a well-recognised phenomenon in many head structures especially the parts of the face, the nasal septum, and the bones of the skull A good account of these is given by R. Martin (Lehrbuch der Anthropologie, pp 341, 638) but he does not mention the condyle of the mandible in his catalogue I have taken the opportunity of measuring the width and anteroposterior diameter of the condyles of several mandibles of both sexes, and find that on one side, usually the right the condyle is both wider from side to side and broader from before backwards by a measurement of the order of 1 mm in the former case and slightly less in the latter The condyles also show differences in shape and outline on the two sides

The general head asymmetry is therefore also applicable to the temporomandibular joint and hence probably also to the soft parts in relation thereto This asymmetry may be hereditary or acquired If acquired it is probably due in part to the effects of masticating more on one side than the other, a feature common enough when carious teeth are present on the opposite side of the jaws This factor alone, however, will not account for condylar asymmetry because alternations are bound to occur in respect to the side used chiefly in mastication in the same individual from time to time Heredity is probably the main factor as in the asymmetries of other parts

I am Sir yours faithfully,
W C OSMAN HILL, M D.

Anatomy Department University of Birmingham

FAT AND TUBERCLE

To the Editor of THE LANCET.

SIR,—I read with great interest Dr W B Vaile's article on Pulmonary Tuberculosis in your issue of Jan 8th I have myself never come across a case of consumption whether in the early or late stages in which the patient did not say " Oh ! I can t eat fats " or the parents (guardians) did not inform the doctor emphatically ' We could nt get the patient to take fats "

I am, Sir, yours faithfully
R MARTIN, L R C P. & S Edin.

Banbridge, Co. Down, Jan 28th, 1927.

be exercised in future in the assembling of the apparatus, and that no further accident of the kind would be allowed to occur.

We have had occasion before to comment on such a catastrophe, and to inquire what would be a safeguard against its occurrence ? The first and best is to test the apparatus each time before use But since it may be impossible to eliminate completely the human element of risk, a final safeguard is to employ fool-proof forms of inhaler, such as those associated with the names of Hewitt, Buxton, and Shipway

THE REGISTRATION OF DEATHS.

A Regulation, dated Dec 31st, 1926, has been made by the Registrar-General, imposing the following requirements upon registrars of births and deaths —

> Where the contents of the medical certificate show that the deceased was not seen after death by the certifying practitioner, and was not seen alive by him within 14 days of the date of death, the death should be reported to the coroner by the registrar

To this new regulation the following instruction is appended —

> In the case of all medical certificates given on the new official form bearing serial numbers with the prefix "Y," the certificate will clearly show whether the deceased was seen after death or not In the case of a certificate given on the forms previously issued with the prefix "X," or any older form, the omission of the words "as I am informed" from the blank in the relevant portion of the form is to be taken as meaning that the practitioner saw the deceased after death and is thus prepared to certify from his own knowledge that death took place But if the registrar has any reason to suspect or believe that the omission was not deliberate, but was due to inadvertence, he should make inquiry of the practitioner in any case where the deceased was not seen alive within 14 days of death

The Secretary of State has recently called the attention of coroners to this regulation in a circular letter which contains the following observations —

> The regulation is based upon the view that responsibility ought not to be accepted by the registrar for registering the fact and cause of a death on the evidence of a certificate given in the circumstances indicated in the regulations, unless he has previously given the coroner an opportunity, at any rate, of investigation or inquiry
>
> When a certificate of death is referred to the coroner under the new regulation, two points may arise (*a*) what proof is there of the *fact* of death—i e , what proof is there that a *body* is lying within the coroner's jurisdiction ? , (*b*) is the *cause* of death sufficiently established or is investigation by the coroner required ?

The first point can be cleared up in various ways, according to circumstances In some cases the coroner may consider it desirable or necessary to ask the doctor why he has not seen the body, and to request him to see it in order that the doctor may amend his certificate in that respect If it is impracticable for the original certifier to see the body, the coroner, in parts of the country where the schedule made by the local authority enables payment for such a service, may upon sufficient occasion ask another practitioner to see the body and report to the coroner as to the fact of death and, if necessary, also as to the cause of death In many cases it may be found upon view by the coroner's officer, in the course of his inquiries that the fact of death is painfully obvious

As regards the second point, the necessity for investigation, it is for the coroner to decide whether the circumstances are such as to require investigation by him, having regard to the duties imposed upon him by law The mere reference of a certificate to the coroner by the registrar does not of itself set up an obligation to investigate Such reference is only one of many means by which a coroner may have his attention drawn to a death and to the possibility that action by him may be necessary It is open to a coroner to decide at once to inform the registrar that in his opinion no inquest is necessary, or to institute such inquiries and obtain such information as he may think requisite before deciding whether to inform the registrar as above or whether to hold an inquest

LISTER CENTENARY.

A committee consisting of representatives of the Royal Society, the Royal Colleges of Physicians and Surgeons, the Royal Society of Medicine, the British Medical Association, the universities and other institutions interested, has been formed to organise a celebration in London of the centenary of the birth of Lord Lister, which falls on April 5th next Representatives of learned societies, universities, and medical bodies in Great Britain and delegates from the dominions and principal foreign countries will be present The delegates will be received by H M the King at Buckingham Palace on April 4th The programme, so far arranged, is as follows —

> April 5th Reception and short addresses by some of the delegates in the large hall of the British Medical Association. Conversazione at the Royal College of Surgeons of England Dinner given by the Merchant Taylors Company, of which Lord Lister was a member
>
> April 6th Memorial service in Westminster Abbey, address by the Bishop of Birmingham Discourses in the Robert Barnes Hall of the Royal Society of Medicine, on Lister as Physiologist, Pathologist, and Surgeon, by Sir Charles Sherrington, Prof W Bulloch, and Sir Berkeley Moynihan Conversazione at the rooms of the Royal Society

The Executive Committee consists of Sir James Berry, Sir John Rose Bradford (chairman), Sir John Bland-Sutton, Prof William Bulloch, Sir Watson Cheyne, Dr H H Dale, Mr R G Hogarth, Sir Berkeley Moynihan, Sir Humphry Rolleston, Sir Ernest Rutherford, Sir Charles Sherrington, Sir Harold Stiles, Sir StClair Thomson, Mr W Trotter, Mr Logan Turner, and Prof A Young

A public meeting in further celebration of the centenary is to be held in the McEwan Hall, Edinburgh, at 8 P M., on Wednesday, July 20th, coinciding with the British Medical Association's annual meeting Earl Balfour will preside, and short addresses will be delivered by Sir William Watson Cheyne, Prof Tuffier, Prof Harvey Cushing, and Dr James Stewart A museum of Lister relics will be on view in the Upper Library of the Old University

A Lister memorial volume has been prepared, edited by Dr Logan Turner, which contains a variety of contributions, including a sketch of Lord Lister's life, given by his former house surgeon, Sir George Beatson, and a series of short personal reminiscences by many old friends from all parts of the world Two of Lister's scientific addresses and a series of letters of general interest are to be incorporated in the book

The sum of £25 and a gold medal will be awarded as a prize for the best essay submitted on the subject "The Influence of Lister on Surgery," by students and graduates of not more than one year's standing of any medical school in the British Empire

---

New Poor-law Hospital in Shropshire —Last week Lady Berwick opened at Berrington, near Shrewsbury, a hospital of 140 beds established by the Atcham Board of Guardians in a former workhouse The buildings have been remodelled and equipped at a cost of about £15,000 and will be used for private paying patients as well as for Poor-law cases The alterations provide for eventual extension to 300 beds

Orthopædics in Warwickshire —It is proposed to establish in Warwickshire a scheme for the treatment of crippled children At present orthopædic treatment is provided by the Coventry and District Crippled Children's Guild and the Nuneaton clinic, but only about a quarter of the county is thus served, though much work of this kind is being carried out voluntarily at St Cross Hospital, Rugby It is proposed to establish clinics at Rugby, Warwick, Stratford-on-Avon, Kineton, and perhaps elsewhere There are 350 crippled children of school age in the county area in the legs, especially the calves, were an almost constant symptom, and associated with considerable tenderness on pressure of the calf muscles. The knee-jerks were diminished in some cases and increased in others."

Dr. Stannus further states in his letter, "observations on a large number of cases have, however, proved to me that the sun's radiations are the only factor in causing a typical distribution of the rash": he then inadvertently disproves the above by stating in the same letter "The affection of the scrotal skin, which was, I think, first pointed out by myself, may result from heat and moisture." I would inquire why, if the scrotal condition is the result of heat and moisture, are the axillæ, which are both moister and hotter, exempt from the eruption?

I have noticed that friction produced by the movement of a loin cloth over the great trochanters and over the prominence of the buttocks, will sometimes cause the appearance in that area of the typical dermatitis in a pellagrous subject. Further, I have knowledge of at least one case, a patient who had been confined to bed in hospital for eight weeks and yet developed a very well-marked pellagrous dermatitis although she had never come in contact with direct sunlight during that period. In my series of cases the skin was usually thickened, rough, coarse and scaly, although each individual had a good wash at least once daily.

I mentioned "slight œdema" occurring in pellagra, it is not, however, a true œdema, for it does not pit on pressure. It is really more of a puffiness of a solid nature, and occurs in patients who have had several attacks of the disease.

The rhagades like soreness at the angles of the mouth, mentioned by Dr. Stannus was present in a considerable number of cases but also occurred in other patients who had no signs of pellagra, and who never, to my knowledge developed the disease.

May I repeat my observations suggested to me that "in pellagra there is a deficiency in thyroid secretion, a neuritis of certain nerves in preference to others and skin lesions corresponding to the distribution of those nerves."

In conclusion, I thank Dr. Stannus for his kindly criticism and I trust my explanation will be acceptable to him.—I am, Sir, yours faithfully,

HORACE M. SHELLEY.

SICKNESS BENEFIT AND UNEMPLOYMENT

To the Editor of THE LANCET.

SIR,—The leading article entitled Health Insurance Funds in your issue of Jan. 22nd comments on the large relative increase in sickness benefit coincident with industrial strife and unemployment. In this connexion the following case occurred at this institution this morning, and is illuminating. A factory worker applying for employment as a domestic was asked when she last saw her panel doctor. The following dialogue occurred:—

Applicant.—This week.

M.O.—What was the matter with you?

Applicant.—Nothing, but I was out of work.

M.O.—But why go to your doctor?

Applicant.—Because it was quicker to get sickness benefit than unemployment benefit, and not so much trouble.

M.O.—But did your doctor know that was your reason for going?

Applicant.—Oh well, you see he always does that for me when I am out of work, and says I am anæmic.

I am, Sir, yours faithfully,

WILLIAM C. FOWLER, M.D.

Pinewood Sanatorium, Wokingham, Berks,
Jan. 26th, 1927.

*** If the applicant was telling the truth she was recording a situation which is almost the despair of the Ministry of Health.—ED. L.

PULMONARY EMBOLISM FOLLOWING OPERATION.

To the Editor of THE LANCET.

SIR,—Dr. W. A. Lister's interesting statistical investigation into the causation of post-operative pulmonary embolism in your issue of Jan. 15th draws attention once more to a subject which has been freely discussed and written of during the last few years. So much indeed has post-operative pulmonary embolism been in the limelight, that there has been a tendency on the part of the profession to give but scant attention to the cases of pulmonary infarction and embolism which occur independently of operation. It has been my experience, ever since influenza "came back" in 1918, to meet with these cases in increasing numbers, so that pulmonary infarction is a common phenomenon in my practice. The infarctions take place in healthy people following attacks of influenza generally during convalescence from an *influenzal tonsillitis*. Other varieties of embolism are also commonly observed, but I am concerned at present with the pulmonary. It is my belief that the great majority of cases of influenzal pleurisy and pneumonia, so called, are really examples of pulmonary infarction. Often the cases are not diagnosed, but in many of the cases one observes the characteristic sticky plum-coloured sputum: it is interesting to note that a good number of these cases are mistaken for phthisis. Further, it is probable that many of the mysterious sudden deaths after influenza, usually ascribed to heart failure, are really due to massive pulmonary embolism. The influenzal origin of the cases is proved by the fact that one sees the cases in rushes during the influenza epidemics and waves, after having gone for months without seeing anything suggestive of a case of embolism. Moreover, at the same time as one is seeing these cases of pulmonary infarction one is seeing cases of embolism in other organs. In other words at certain seasons embolism becomes very prevalent. The natural conclusion can only be that influenza is an important factor in the causation of embolism. In what way is this brought about? Surely by an increased coagulability of the blood. That the blood is profoundly affected is shown by the fact that several of my cases of pulmonary infarction have shown well-marked jaundice, most probably due to a hæmolytic streptococcus associated with the influenzal attack.

In what way do the above facts throw light on the cases of pulmonary infarction that occur after operation? Personally, I can count the number of post-operative cases on my fingers, but I can say that whenever I see a case of post-operative pulmonary infarction at the hospital to which I am attached, I see outside the hospital at the same time similar cases of infarction in patients on whom no operation has been performed: these patients are suffering from influenza.

To give an example of what I mean. In the 19 days from August 30th to Sept. 17th, 1925, when influenza was very prevalent in my practice, I saw (1) a fatal case of pulmonary embolism after childbirth; (2) a case of pulmonary infarction with blood sputa after an operation for hernia; (3) a cerebral embolism with ensuing cortical hemiplegia; and (4) a cerebral embolism fatal in 12 hours. I had seen nothing like a case of embolism since the preceding May. In this month influenza was epidemic, and I saw three cases of embolism. I have noted the same thing many times. Again I remember well a fatal case of pulmonary embolism (verified by autopsy) in a patient the day before he was to have been operated on for chronic appendicitis. If the fatal event had been delayed another day the operation would have been held accountable. Do not the above facts suggest that the operative cases are in some way related to the non-operative cases? I am certain that the importance of influenza in this respect has been overlooked. At a recent discussion at the

BLOOD PRESSURE IN INFLUENZA

To the Editor of THE LANCET.

SIR,—Referring to Dr Shore's letter on the need for keeping convalescents from influenza in bed, and for the administration of tonics until the low systolic blood pressure has risen, I should like to point out that a condition of chronic low blood pressure is far from uncommon, and occurs in people in whom it would not be expected I have a dozen patients in my practice whose systolic blood pressure has to my knowledge never risen above 105 mm Hg for two years If such a patient were to contract influenza he might be condemned to a decidedly long convalescence Very little seems to be known about this condition of chronic hypopiesis It seems to be more common in males than females, 10 males and 2 females in my cases, and their aged range from 30 years to 80 years All of them are active and earn their own livings, including the man of 80, who is in full work as a surveyor Four of them are farmers and walk many miles a day They all live hygienic lives and six of them have always been non-smokers

The symptoms most commonly complained of are (1) giddiness when assuming the erect posture, (2) lassitude and a vague feeling of being out of sorts They sweat a good deal during physical exertion These cases are often slightly hypochondriacal, they are quiet and reserved in temperament and not given to enthusiasm They exhibit an astonishing tolerance of belladonna, including the patient of 80 years I have not found any decided benefit with the usual tonic-treatment and hygienic measures, such as cold or tepid baths and liberal diet Daily injections of pituitrin and adrenal extract were tried, but apart from the immediate rise of blood pressure for an hour or so no benefit resulted

I have recently treated eight of these cases with "coramine" (a 25 per cent solution of pyridine-β-carbonic acid diethylamide) A dose of 25 minims was given twice a day by the mouth and continued for 14 days In every case there was a great improvement in the patients' sense of well-being and energy The giddiness disappeared In all cases but one the systolic blood pressure rose and was never less than 120 mm Hg, and in some cases the blood pressure rose to 130 and 140 mm Hg It was noted that very little or no improvement took place during the first week of administration in most of the cases In regard to the permanence of the raised blood pressure after the "coramine" has been discontinued these chronic cases of long standing appear gradually to revert to their previous state in the course of four or five weeks

I have not yet used "coramine" for the hypopiesis resulting from influenza

I am, Sir, yours faithfully,
P D H CHAPMAN, M B, B Ch Camb
Bridlington Jan 31st, 1927

NEW NAMES FOR OLD DISEASES.

To the Editor of THE LANCET

SIR,—In the discussion following Sir Humphry Rolleston's address on Changes in the Clinical Aspects of Diseases (THE LANCET, Jan 15th) I alluded to a possible source of confusion arising from occasional change in name of diseases, and I hope you will allow me to mention here one or two other examples of such a change in names The rare disease in children to which I alluded was named "erythrœdema" in 1914 by Dr H Swift, of Adelaide, Australia An objection to the name was that there was no obvious œdema, though the extremities might appear turgid. Recently, however the disease has been called by a still more unsuitable name, "acrodynia"[1] The latter name had been previously bestowed on the great epidemic disease (hardly likely to be identical) which attacked about 40,000 persons in Paris during less than a single year (1827-28) The names of well-known diseases such as measles and scarlet fever can hardly be altered, but uncommon and relatively little-known diseases can be altered by any author who writes on them A recent example is that of tuberous sclerosis of the brain, often associated with Pringle's multiple telangiectatic type of adenoma sebaceum of the face Whenever the latter was present in the subjects of epilepsy or mental deficiency the presence of tuberous sclerosis of the brain was suspected, but could hardly be proved without a post-mortem examination Dr E B Sherlock,[2] not contented with these names, coined a new one, "epiloia," which he regarded as suitable, being "short, unmeaning, distinctive, and capable of forming an adjective" Thus, at recent meetings of the Royal Society of Medicine[3] cases have been shown under the heading, "epiloia" It seems inconvenient, to say the least, that, when careful studies of the subject have been published in various countries under the heading, Tuberous (or Tuberose) Sclerosis, the latter name should be arbitrarily displaced in favour of "epiloia" recommended by its introducer as being "meaningless" In 1920, when Sir Arthur Keith proposed the name "diaphysial aclasis" for the disorder of growth generally known as "multiple exostoses," there was at the back of his suggestion at least an interesting scientific theory of causation Moreover, it is possible that the developmental disorder in question may occasionaly occur without the formation of actual exostoses[4] But there is no excuse of the kind for "epiloia"

I am, Sir, yours faithfully,
F PARKES WEBER
London, W, Jan. 18th, 1927

PELLAGRA IN NYASALAND

To the Editor of THE LANCET

SIR,—I beg your permission to reply to criticisms made by Dr Hugh S Stannus in reference to my article on Pellagra in Nyasaland which appeared in your issue of Jan 8th I read the first communication Dr Stannus made to the Royal Society of Tropical Medicine and Hygiene on Pellagra in Nyasaland with very great pleasure and I have the fullest admiration for the accurate description of the disease that he gave on that occasion I did not read his second communication on the same subject until quite recently, and I was unaware that cases of the disease had been discovered in members of the general population previous to my own observations However, my work confirms his original obervations on that point

Dr Stannus seems to imply in his letter that I claim to be the first observer to formulate the theory that the pathological lesions in pellagra are due to a toxin, whereas I merely try to prove by my observations that the toxin acts upon various systems in the body and so produces the characteristic features of the condition I am convinced that one of the chief actions of the toxin is to interfere with the correct functioning of the thyroid gland, hence my comparison between certain signs in pellagra and other signs in myxœdema Further, the above theory has received substantial support from post-mortem evidence the source of which I stated in my article My observations are the result of clinical investigation, and whatever the pathological changes in the nervous system may be, there are signs of a peripheral neuritis in the early stages of the condition, to quote Dr Stannus, "pins and needles, and burning pains in the soles of the feet, especially along the outer margin and in the pulps of the toes, pains

DEATHS IN THE SERVICES

Surg Comdr Alexander Gordon Andrews, R N (retd) who died on Jan 16th entered the Royal Navy as a surgeon in 1881 and in the following year was appointed to H M S *Monarch* Later he served in the cruiser *Pylades* in Australia, and was staff surgeon of the *Terrible* during the South African War and the Boxer rising He was present with the naval brigade at Tientsin In 1903 he was appointed senior medical officer of the *St Vincent*—boys' training ship at Portsmouth—and in 1904 took charge of the Royal Naval Hospital at Yarmouth From 1909 he served in the battleship *Superb*, and from 1911 as fleet surgeon of the Dockyard, Malta In 1914 he joined the battleship *Prince George* and in the following year was appointed for special service at Chatham He retired in 1916

DENTAL WORK IN BIRMINGHAM —Last year at the Birmingham Dental Hospital there were nearly 36,000 operations A new department for dental bacteriology was opened during the year

Medical News.

UNIVERSITY OF CAMBRIDGE —At a recent Congregation the following degree was conferred —

M.B , B Ch —R T Mummery

ROYAL COLLEGE OF PHYSICIANS OF LONDON —An ordinary quarterly *Comitia* of the College was held on Jan 27th, Sir John Rose Bradford, the President, being in the chair The following candidates were admitted as members —

Ahmed Khalil Abdel-Khalik, William Arthur Bourne, Hugh Nash Bradbrooke, John Alexander Charles, George Coelho, Thomas Reginald Davies Charles Sydney Douglas Don, John Hartley Gibbens William Gunn, George Stiven Halley, John Reginald Brock Hern, Alexander Mills Kennedy, Robert Albert Edward Klaber, Ardeshir Jehangirshah Kohiyar Geoffrey Laurence Samuel Kohnstam, Robert Daniel Lawrence, Maurice Mitman, Edward Clark Noble, Robert James Valentine Pulvertaft William James Reid, Olive Rendel, Navroji Kharshedji Sahiar, Lewis Herbert Savin, Kenneth Shirley Smith, Kenneth Andrew Soutar Hilda North Stoessiger, Clara Dunbar Tingle, Robert Arthur Walsh, Robert Goege Ranyard West, Cecil Oswald Young

Dr W C Bosanquet, Dr J H Sequeira, Dr F Craven Moore, and Dr J A. Nixon were elected Councillors to take the places of Dr F J Poynton, Dr J H Abram, Dr T Wardrop Griffith, and Sir Walter Morley Fletcher —Sir Francis Champneys was re appointed a representative of the College on the Central Midwives Board —The resignation of Sir Humphry Rolleston of the post of representative of the College on the General Medical Council was received, and a vote of thanks was accorded to him Dr E Farquhar Buzzard was elected as his successor —Dr Stanley Barnes was appointed a representative of the College on the Court of Governors of the University of Birmingham in place of Dr A. F Voelcker, whose term of office expired on Dec 31st, 1926 —Dr J H Abram was reappointed a representative of the College on the Court of Governors of the University of Liverpool —The resignation of Sir William Hale-White of the post of representative of the College on the Central Council for District Nursing in London was received, and Dr A S Woodwark was elected in his place —The acceptance by Mr F H Maugham, K C , of the post of Senior Standing Counsel to the College was reported —The President announced that he has appointed Dr J F Gaskell to deliver the Bradshaw Lecture for 1927, and that the Council have appointed Dr F A E Crew of the Animal Breeding Research Department of Edinburgh University, to be Milroy Lecturer in 1928 —A communication was received from the Ministry of Health asking the College to nominate a representative to serve on an Advisory Committee of Clinical Experts to consider the details of the proposed alterations to be suggested by the British Government at the forthcoming Revision of the International List of Causes of Death, by the Health Section of the League of Nations at Geneva Dr Robert Hutchison was appointed Dr S Monckton Copeman was appointed to represent the College at the Congress of the Royal Sanitary Institute to be held at Hastings from July 11th to 16th, 1927 —The President, Sir John Rose Bradford, was elected as a delegate to the celebration of the Lister Centenary in April 1927 —A report was received from Sir John Broadbent, who represented the College at the celebration of the Centenary of Laennec in Paris in December, 1926

At the same meeting of the Comitia licences to practise were conferred upon 126 candidates (21 women and 105 men) who have passed the recent Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the by-laws of the College The following are the names and medical schools of the successful candidates —

W M Abdel Malek Birmingham G M Addison Cambridge and St Thomas's J C B Allen Sydney and Middlesex I S Alman Berlin and Middlesex H Archer Bristol F F Augsburger Lausanne M T Aung Guy's G C Babington St Thomas's, D H Belfrage Cambridge and St George's R N Bery and R V Bowles Univ Coll Winifred P Brinckman Bristol A H Bruce Guy's S M Burrows St Thomas's C P Campion Cambridge and Univ Coll Margaret E M Carter St Mary's B M Clark St Bart's H H Cohen London I Collin Russ Middlesex C L Cope Oxford and Univ Coll J H Couch Toronto Geraldine H Cowle Royal Free and Westminster R D Curran Cambridge and St George's C Davies Birmingham J Dean St Bart's Daphne W Dear King's Coll J H [illegible] Donelland Cambridge and St Bart's A O Dreosti St George's J Ellison Oxford and Leeds D K Evans Cardiff Enid C Evans St Andrew's and Westminster F S Evans and F M M Eyton Jones St Bart's A P Farmer and G M FitzGibbon St Thomas's A M Fleming Middlesex A B Follows Liverpool Elsie G M Ford Leeds D Gamsu Durham H G Garland Leeds

Royal Society of Medicine, very little attention seemed to be paid to Featherstone's[1] suggestion that colds and influenza played a great part in the production of post-operative pulmonary complications, though I am convinced he was nearer the mark than many of the other speakers

There is no doubt that there has been a great increase in the number of cases of *medical* pulmonary infarctions seen in practice, and Sir C Gordon-Watson has shown that at St Bart's Hospital, at least, there has been a relative increase in the *surgical* embolisms This is surely to be expected when influenza is so constantly with us It would certainly be rather wonderful if out of the thousands of patients undergoing operations daily none were suffering from the blood changes that must be present in a large proportion of the population at certain (influenzal) seasons To sum up, post-operative embolism must be, in certain cases at least, a coincidence which has nothing really to do with the operation It would have been extremely interesting if Dr Lister's investigation had shown whether the cases he analysed occurred most frequently at the dates of the well-marked influenza epidemics

What of the prevention of these cases? I now give potassium citrate as a routine to all my influenza cases With regard to the exercises that are advocated after operation, I would only state that my experience shows that it is the restless, excitable patient, rather than the placid contented individual, who is liable to embolism

One moral can be drawn—no operations but the most urgent should be performed during the influenza seasons —I am, Sir, yours faithfully,

Aberdare, Glam , Feb 1st, 1927 AMBROSE W. OWEN

IMMUNITY TO IMPLANTED TUMOURS.

To the Editor of THE LANCET

SIR,—I should like to endorse Dr Mottram's remarks in his letter in your last issue It has, of course, been known for many years that a limited amount of growth will take place in serum, but the majority of tissue culture workers have discarded this medium as the growths obtained by its employment are more of the nature of what Fischer has termed outwandering of cells rather than real growth In our experience, all strains of carcinoma and other epithelial tissues, whether grown in liquid or solid media, grow either as continuous sheets or in the form of long finger-shaped processes The cells described and figured by Dr T Lumsden we regard in our cultures as fibroblasts and cells derived from the stroma, these are frequently seen in cultures in which the true cancer cells are growing badly So far as I am aware there is no evidence that inoculation of such outwandering cells *only*, free from the original fragment into mice, ever gives rise to tumour formation

Inoculation of the sheet type growth from, say, carcinoma 63 into mice produces typical tumours in the usual way I think Dr Lumsden's figures emphasise the necessity of working with pure cultures in this type of experiment

I am, Sir, yours faithfully,
A H DREW

Stroud Laboratories, Mill Hill, N W , Feb 1st, 1927

BAY MOUNT, PAIGNTON

To the Editor of THE LANCET

SIR —Thank you for the kind reference to the Bay Mount Annual report, which you make in THE LANCET this week I appreciate the encouragement greatly May I, however, point out that the reference to injections and tonics might be read by a nervous patient as meaning that the injections were also given two hourly, whereas the injections are only given twice or thrice daily according to circumstances Critical readers might consider that to fail to cure two out of seven cases was not a good record Again, in the reference to five cured cases out of seven, it is not quite clear that one case was not treated at all because he was too ill, and that another did not present himself for treatment, but for a change only. He had a special permit to obtain morphine, for reasons of health, and it was not considered advisable to withdraw his drug He came to Bay Mount for a few weeks change while his wife was changing houses and preparing a new home for him This patient has since died

The five treated cases all did remarkably well, and left Bay Mount in good health and free from any desire for the drug

I am, Sir, yours faithfully,

TRAUMA AND TUMOUR

To the Editor of THE LANCET.

SIR,—In reply to Sir Lenthal Cheatle, may I state that for some months I have been collecting cases of cancer arising in wounds received during the late war and so far have obtained three undoubted cases Probably many more could be found, and I should be glad to obtain particulars of them They are of interest as throwing light upon the length of the period of cancer induction in man The subject of cancer arising in scars other than those due to burns is discussed in the *Cancer Review* (1926, i, pp 108 and 183), Abstract 169, of a paper by Bang, and Abstract 327 of one by Iwamoto, and (1927, ii, p 55) Abstracts 102 and 103 of papers by Tow and Itoh, and by Dubreuilh and Maginel respectively Since the latent period seems to be from 12 to 40 years, it is still perhaps somewhat early to expect many cases of malignant disease arising from wounds received in the last war

I am, Sir, yours faithfully,
H. J B FRY.

The Cancer Hospital Fulham road, London,

A MUSEUM OF ECONOMIC BOTANY

A COLLECTION of economic plants made by Dr. J B Hurry was formally handed over to the County Borough of Reading on Jan 25th to form a permanent part of the municipal museum Dr Hurry's hobby of growing plants that minister to the welfare of mankind dates back twenty years or more, when he began to import specimens from various countries, especially from the tropics, compiling at the same time a museum of economic products derived from them As time went on he accepted contributions from the Empire Exhibition, the Imperial Institute, the Royal Botanic Gardens at Kew, the Musee Colonial of Paris, and the Reading University He was actuated by the feeling that botany is essentially a subject to be learnt from the life rather than from books, and that a collection of well-chosen specimens should be useful in cultivating the power of observation and stimulating the imagination of children of school age In the new room of economic botany Dr Hurry's collection is arranged under the seven sections of Food Products, Nuts, Fibres, Woods, Gums and Resins, Medicines, and Dyes, and apart from the exhibits there is a duplicate series in drawers of specimens which can be actually touched and examined In a lecture on Economic Botany, which followed the formal opening of this room, the Headmaster of St John's School, Reading, described the exhibition as a carefully conceived nucleus which should prove of considerable value for teaching purposes It is no doubt well that the children of this country, who only see the limited flora of the temperate zone, should gain some acquaintance with the whole gamut of plants which provide food, clothing, shelter, fuel, light, health, or ornament in various parts of the British Commonwealth

A supplementary list of licentiates will be issued later for those candidates who had not completed their examination on Jan 27th

The undermentioned diploma was conferred (jointly with the Royal College of Surgeons) upon the following candidates —

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY

M Anton, T R Aynsley, Doris M Baker, K R Chaudhri, M Fine, Winifrede M Fish, J C Gillespie B Gluck, B Graves, J W Harris, H N Ingham G D E Jones, Edith M F McGill, H D Patel N N Ray, A H S Richardson, A F Senewiratne, T Shukla, S Singh, Caroline M Stenhouse, and D A Williams

Diplomas in Public Health, in Laryngology and Otology, and in Psychological Medicine were also conferred on candidates whose names have already been announced (The Lancet, Jan 22nd, p 209)

Society of Apothecaries of London—At recent examinations the following candidates passed in the undermentioned subjects —

Surgery—G W Ayres, St Mary's Hosp, B Best, Bristol and Liverpool, N S J Roberts (section II) Middlesex Hosp, B Rosenzvit, Royal Free Hosp, M T Y Selim, Liverpool, and W D Williams, London Hosp

Medicine—L G Apps, London Hosp, L O Jaggassar, St Mary's Hosp, L W. Rose, Guy's Hosp, S E Tremellen, King's College Hosp, and S Wray, Manchester

Forensic Medicine—L G Apps, London Hosp, W A A Collington, Guy's Hosp, S E Tremellen King's College Hosp, and E H Waller, Charing Cross Hosp

Midwifery—G W Ayres, St Mary's Hosp, P V Bamford, London Hosp, R Bobo, Paris, S K Rigg, Bristol, and K. Roberts, Liverpool

The Diploma of the Society has been granted to the following candidates, entitling them to practise medicine, surgery, and midwifery R Bobo L O Jaggassar, K Roberts, S E Tremellen and W D Williams

Royal Institution—On Tuesday, Feb 8th, at 5 15 P M, Prof Julian Huxley will lecture on Animal Growth and Development

Royal Statistical Society—The Council of this Society will in 1927 award the Frances Wood Memorial Prize, value £30, for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the wage-earning classes Particulars of the competition, which is only open to specified groups of candidates, may be had from the hon secretaries of the Society, 9, Adelphi-terrace, London, W C 2

University of London—At a meeting of the Senate held on Jan 26th, Sir William Beveridge, the Vice-Chancellor, in the chair, the following appointments were made Mr H L. Eason to represent the University on the General Medical Council, Sir William Collins to be a member of the Royal Sanitary Institute and Sanitary Inspectors' Examination Joint Board, Sir Holburt Waring to represent the University at the celebration of the centenary of the birth of Lord Lister, to take place in London on April 5th, and Dr M E Delafield to be a representative (in respect of University College) at the Congress of the Royal Sanitary Institute at Hastings in July

A course of three lectures (illustrated with lantern slides) on Allergic Diseases caused by Factors of Climate, will be given by Prof W Storm Van Leeuwen, of the University of Leiden, at St Thomas's Hospital (Sherrington School of Physiology) on Monday, Tuesday, and Wednesday, Feb 14th, 15th, and 16th, at 4 P M Admission free, without ticket

University College—A course of six public lectures on Reproduction will be given by Dr A. S Parkes at 5 P M. on Mondays, Feb 7th, 14th, 21st, and 28th, and March 7th, and 14th Dr E D Adrian will lecture on the Action of the Sense Organs on Wednesdays, Feb 9th, 16th, and 23rd at 5 P M

West Kent Medico-Chirurgical Society—A meeting of this Society will be held at the Miller General Hospital, Greenwich, on Friday, Feb 11th, at 8 45 P M Mr Zachary Cope will give an address on Surgical Emergencies in General Practice

Royal Medico-Psychological Association—The next quarterly meeting of the Association will be held on Feb 16th at the Cheshire County Mental Hospital, Parkside, Macclesfield Prof T H Pear will read a paper on Recent Investigations on Visual Imagery with Special Reference to Hallucinations

Hamilton Drummond Memorial Fund—A general meeting of the subscribers to this fund will be held in the library of the Royal Infirmary, Newcastle-upon-Tyne, on Feb 7th, at 7 30 P M., in order to approve a scheme for the memorial, to appoint trustees for the Fund, and an executive committee

General Lying-in Hospital, York-road—The new building of the Post Certificate School will be opened by Mr Neville Chamberlain, Minister of Health, on Tuesday, Feb 8th, at 3 15, when the presentation will be made to Sir Francis Champneys, President of the hospital, by Mr H W Lydall, the solicitor of the donor Dr John S Fairbairn will take the chair and the ceremony will be followed by a reception

Condition of County Clare Hospitals—The Minister for Local Government in the Irish Free State is to be asked for a free grant towards putting certain of the hospitals in Clare into "fair condition" The Kilrush and Ennistymon hospitals under the County Clare Board of Health are officially stated to be "fast falling into ruin," while the County Hospital itself is "in urgent need of extensive repairs" Another institution is afflicted with a plague of rats which run about the wards, eat the nurses' clothing, and "make themselves at home in every room"

Fellowship of Medicine and Post-Graduate Medical Association—Dr W M Wanklyn will lecture for the Fellowship on Exanthemata with Special Reference to Small-pox, on Feb 10th, at 5 P M, at the house of the Medical Society of London, 11 Chandos-street, Cavendish-square Mr W H Trethowan will give a special demonstration in orthopædic surgery at the Royal National Orthopædic Hospital on Feb 10th, at 3 P M, and a special lecture on Causes and Treatment of Vomiting in Children will be delivered by Dr C C Beatty at the Royal Northern Hospital on Feb 15th at 3 15 P M. All these lectures and demonstrations are free to members of the medical profession From Feb 7th, for two weeks, the Paddington Green Hospital and the Victoria Hospital will jointly hold an all-day course in Diseases of Children, and beginning on the same date the London Lock Hospital will hold a four weeks' course in Venereal Diseases, consisting of clinical instruction in the out-patient department in the afternoon and evening and special lectures at intervals The Royal Northern Hospital is undertaking a special course for practitioners for one week from Feb 21st lectures will be given in the afternoon and the rest of the time will be devoted to teaching in the wards and various departments of the hospital The Fellowship arranges practical courses in anæsthetics and obstetrics, and arrangements can be made for clinical assistants Syllabuses of Special Courses, the General Course Programme and copies of the *Post-Graduate Medical Journal* may be had from the secretary of the Fellowship at 1, Wimpole-street, London, W 1

Anti-Venereal Campaign in Manchester—The Manchester Public Health Committee is launching a campaign for the prevention and cure of venereal diseases There will be two addresses daily in various public halls in the city from Feb 14th to 19th, the one in the afternoon will be for women only, and the one in the evening for mixed audiences Each address will be illustrated by cinema films, and there will be no charge for admission

Further Extension of Queen Mary's Hospital At the annual dinner of this hospital last week, Prince Henry, the President, stated that the out-patient department is the fourth largest in London and the maternity department the fourth largest in England During the last four years three new wings have been erected at a cost of £120,000, and a fourth is now being built which will accommodate a solarium, an enlarged X ray department, and a new medical ward for children

Gift to the University of Edinburgh—The International Education Board of New York, one of the Rockefeller Foundations, has informed the University of Edinburgh that it is making a gift of £74,000, to be used as a contribution to the cost of a new department of zoology, to be created at the King's Buildings of the University at Craigmillar Of this sum £38,000 is for building, £10,000 for equipment, and £26,000 for endowment The University has £41,000 in hand for building, so that a total sum of £79,000 will now be available for this purpose The University Court has gratefully accepted the gift, and the construction of the new department will begin at once

Action against Surgeon for Operation without Consent—At the Liverpool Assizes on Jan 27th a case was tried in which a patient sued Mr St George Wilson for negligence, and for performing an operation upon her without her consent at the Samaritan Hospital for Women. The statement made in court was to the effect that the patient was examined by Mr Wilson at the hospital in October, 1923, and by arrangement returned the following day for examination under an anæsthetic She was complaining of symptoms of cystitis of great urgency, and during his examination Mr Wilson made up his mind that it would be wiser to establish free drainage of the bladder at once and thus avoid giving a second anæsthetic. When doing this he was unaware that the patient had not signed the permission book as the routine practice at the hospital requires, he had explained to her that a serious operation would be required for relief of the toxæmia from which she was suffering, but by some inadvertence no written consent had been obtained A suprapubic cystostomy was performed, and five weeks afterwards the patient was transferred to a general hospital where a "hydronephrotic" kidney was removed Owing to a persistent vesical fistula she still has to wear a suprapubic apparatus Not until a year after operation was any complaint made, and a further period of two years elapsed before action was taken At the hearing the plaintiff withdrew any suggestion that the operation had not been skilfully performed, but maintained that she had never consented to it, and that in fact she had not realised until some time later that it had been done In answer to questions she said that if she had been told beforehand that an immediate operation was necessary she would have consented to it. Even if she had been brought out of the effect of the anæsthetic and had been told that an operation was imperatively necessary, she would have consented to go under a second anæsthetic again and be operated upon She agreed that the initial operation had probably saved her life Dr H H McWilliam, senior medical officer of the Walton Infirmary, said that the operation had been necessary to save life On the plaintiff's behalf Mr Rice Jones said that the body of a man or woman was sacred, and no one had any right to meddle with it So far back as 1767 it had been held that a surgeon ought not to operate without the patient's consent It was necessary for a person to be told that an operation was about to be performed in order that he or she might take courage or get a second opinion. Mr F A Jeans, honorary surgeon at the Royal Infirmary, was called in Mr Wilson's defence He stated that so far as he could judge from the history he would have acted as Mr Wilson had done, in the interest of the patient He elaborated this point when a supposititious case was put before him by the judge, of a patient under an anæsthetic being subjected to an operation the necessity for which was only found in the course of the proceedings Mr Jeans pointed out that in such a case there was undoubtedly a clash between the interests of the patient and the interests of the surgeon Mr Justice Wright, addressing the jury, said that no surgeon, however well intentioned he might be, had any right to perform an operation without the consent of the person concerned After a long retirement the special jury found for the defendant with costs, appending the rider "No doctor ought to operate without getting consent," to which the Judge added, "if it can be avoided"

Comment on this case will be found on p 309

University of Manchester—Dr William Fletcher Shaw, who has been professor of obstetrics and gynæcology in the University since May, 1925, has been appointed to the chair of clinical obstetrics and gynæcology in succession to the late Prof W E Fothergill Dr Daniel Dougal, who is at present lecturer in obstetrics and gynæcology in the University, has been appointed to the chair of obstetrics and gynæcology vacated by Prof Fletcher Shaw

Dr Dougal was educated at the Manchester Grammar School and in the University of Manchester He was awarded a gold medal for his M D thesis and is the author of many articles on obstetric and gynæcological subjects He had a distinguished military career, and is at present Lieut -Colonel and Commandant of the Second Western General Hospital Before the war he was a demonstrator in anatomy in the University, and since 1920 has been continuously associated with the gynæcological department as demonstrator, assistant-lecturer, and lecturer Among other appointments which he holds are those of honorary surgeon to the St Mary's Hospitals for Women and Children, Manchester, and honorary gynæcological surgeon to the Manchester Royal Infirmary

Questionaire on White Flour—The National Association of British and Irish Millers has issued a series of questions to over a thousand doctors in every county of England, Scotland and Wales, the names being chosen at random from the Medical Directory The Association is stated to be "desirous of obtaining representative and authoritative medical opinion on the value of the type of bread which has been evolved by the public requirements of many years, and for the making of which nearly all its mills are specially equipped" The circulated letter goes on to say that "in one or two cases, unfortunately, statements calculated to create the gravest alarm in the minds of the public have been made by distinguished members of your profession, active and retired The millers desire to serve the public faithfully, and to give them good flour It is apparent however, that the intricate organisation of a great national industry cannot be dislocated by demands that may be merely transient—and which are probably unsupported by the medical profession as a whole—without serious results to the industry and to the poorer classes of bread buyers" The questions to be answered are the following:—

1 Do you concur in the statement made by the President of the New Health Society (*Daily Mail*, Oct 21st, 1926), that "the curse of our age is that we are provided with white bread"?

2 Do you consider that having regard to the average variety of diet now enjoyed by people in this country, white bread is a good and nutritious food?

3 Do you consider that white bread as part of an ordinary mixed diet is likely to lower the standard of national health?

4 Do you personally eat white bread?

It is not intended that in any circumstances the names of those sending replies shall be revealed

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 22ND, 1927

Notifications—The following cases of infectious disease were notified during the week. Small-pox, 558 (last week 675), scarlet fever, 1455; diphtheria, 1019, enteric fever, 22, pneumonia, 1984, puerperal fever, 24, puerperal pyrexia 136; cerebro-spinal fever 11; acute poliomyelitis, 17, acute polio-encephalitis, 2, encephalitis lethargica 32, dysentery, 4, ophthalmia neonatorum, 108 There was no case of cholera, plague, or typhus fever notified during the week

The cases of small-pox were reported from the same counties as last week, with the addition of one case from Stafford (Stone R D), but Durham reported 313 instead of 349, and Yorks West Riding, 161 instead of 266, the number of notifications from Sheffield being nearly 100 less than in the previous week. In Northumberland however, 24 cases were notified as against 10 last week, 15 of them from Ashington

Deaths—In the aggregate of great towns including London there was no death from small-pox, 2 (0) from enteric fever, 43 (0) from measles 4 (1) from scarlet fever 66 (32) from whooping-cough, 39 (9) from diphtheria 44 (10) from diarrhœa and enteritis under 2 years, and 470 (197) from influenza The figures in parentheses are those for London itself The influenza deaths for the last six weeks have thus been 60 69, 86, 173, 326, 470—and 725 has been given verbally as the figure for the next week

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

SOCIETIES

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Stewarton (Ayrshire) Bilston (Staffs) Godalming (Surrey) Presteign (Radnorshire), Silsden (Yorks W Riding) and Williton (Somerset)

Births, Marriages, and Deaths.

BIRTHS

Bate —On Jan 28th at Fourth avenue Hove the wife of Geoffrey Bate F R C S E , of a daughter

MARRIAGES

Bevan—Combe —On Jan 22nd at St Peter s Church Brockley Frank Arthur Bevan M B B S to Mary elder daughter of the late Charles E Combe L D S and Mrs George Read of Holly Bank Adelaide road S E

Dawson—Paton —On Jan 29th at St Matthew s Church Denmark Hill Dr Wm S Dawson to Gladys Lyle Paton

Kennedy—Hart —On Jan 26th at St Laurence Church Measham Leicestershire George Rollo Kennedy M B Ch B (Edin) of Claverley Salop to Mary Hampton only daughter of the late Dr G S Hart and Mrs. Hart and granddaughter of the late Dr J W Mulligan of Abersychan, Mon

Porter—France Hayhurst —On Jan 26th at St Peter's Wrockwardine Wellington Salop Cecil Petyn Porter M B Ch B of Kidderminster to Cecily younger daughter of the late Rev Hesketh France Hayhurst and Mrs France-Hayhurst

DEATHS

Bradshaw —On Jan 25th at The Tower Mold Thomas Robert Bradshaw M D F R C P late of Rodney-street, Liverpool aged 69

Elliott —On Jan 26th at his residence "Cranford South drive St Anne s-on the Sea Arthur Campbell Elliott M B C M M B E aged 61 years

Fletcher —On Jan 26th John Corbet Fletcher, M D C M , aged 84

Fletcher —On Jan 29th after long illness Martha Parker Fletcher for 51 years beloved and devoted wife of the late John Corbet Fletcher aged 73

Fry —On Jan 29th at Brentwood Langley road Surbiton. John Farrant Fry L R C P Lond M R C S Eng aged 74

Hosford —On Jan 24th at 37 Richmond Hill Thomas Stroud Hosford M R C S L R C P aged 83

N B —A fee of 7s 6d is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Comments, and Abstracts.

RADIOGRAPHY AS IT AFFECTS THE ASSURABILITY OF OPERATORS [1]

By Stanley Melville, M D Brux , M R C S Eng ,

BARRISTER-AT-LAW RADIOLOGIST, ST GEORGE S HOSPITAL AND HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON

It has been my lot to try to do something for the greater safety of the X ray worker and I hope to demonstrate to you that under certain know conditions such a life is a perfectly suitable risk Ten years ago even six years ago I dared not have suggested such a thing All who have been injured (so far as my investigations have carried me) received their injuries before we had any definite knowledge as to the precise nature of the injuries or how to combat them Even the physical nature of X rays was, until recently, much in dispute Only within the last year have we known that they are ether waves or disturbances of the ether akin to light but with a wave length some 10,000 times less than similar disturbances known as light

Until quite recent times, too most if not all X ray work has been carried out in small ill-ventilated rooms and with very inadequate or no protection

I think it may be well if I direct attention to the discussion of the two main points (1) the effect of X rays upon the tissues and upon the blood , (2) the present position as regards protection

(1) *Effect upon the Tissues*

The chronic radio-dermatitis of X ray operators is the result of small frequently repeated doses the first effect of which is a stimulation of epithelial growth The result of this is that the skin becomes dry and hard with the formation of warty growths Changes in the blood-vessels take place and the exposed parts (especially the dorsum of the hands) become red and mottled At a later stage in some few cases ulceration has taken place which has developed into a carcinomatous growth In the "Acta Radiologica" Amundsen in 1924 published the results of his investigations lasting over a number of years on the blood of an X ray staff He found that there was a definite deviation from the normal in the whole of the personnel as follows (1) diminution in the actual number of white cells , (2) reduced percentage especially of the polymorphonuclears (3) no alteration in the hæmoglobin He found that the blood picture definitely improved after a period of cessation from work but especially *after the protective arrangements had been improved*, the latter a most important point as I shall hope to show you

As a result of innumerable counts made in many institutions all over the country the following has I think been established Over-exposure under faulty working conditions shows the following changes (*a*) invariable leucopenia the white cells falling to less than 50 per cent of the normal, the reduction falling chiefly upon the polynuclear leucocytes and the lymphocytes (*b*) following this a gradual decrease in the total number of the red blood corpuscles and in the hæmoglobin percentage With undue radiation (and especially where the bone-marrow or the spleen has received the chief dosage) a much more serious condition has been recorded Severe aplastic anæmia ending in death was seen in certain of the workers at the Radium Institute and among private persons who were engaged in either radium or X ray work

I come now to the second and, to my mind the more hopeful part of my paper

(2) *The Present Position as Regards Protection*

In 1920 the problem of adequate protection had assumed large proportions Not only were there some definite cases of aplastic anæmia among the workers at the Radium Institute but in the same year there occurred the untimely death of Ironside Bruce a *comparatively* young and energetic radiologist, from the same dire complaint About that time having heard a rumour to the effect that there was likely to be a great crusade by the Press against the use of X rays and radium, I determined to get something started by way of counterblast I found all my colleagues in agreement to organise the X ray and Radium Protection Committee We were fortunate in getting as our Chairman Sir Humphry Rolleston The committee was thoroughly representative of British radiology, the members being in the first instance elected by the Rontgen Society the Electro-therapeutic Section of the Royal Society of Medicine and by the British Association for the Advancement of Radiology and Physiotherapy. Dr J C Mottram joined us as representing the Radium Institute, and he undertook the investigation into the blood condition Prof. S Russ represented the Institute of Physics, and the National Physical Laboratory was represented by Dr G W C Kaye, to whom we owe a very great amount of the experimental work upon which the report was finally built

---

[1] An address read to a meeting of the Assurance Medical Society on Jan. 5th.

No committee ever worked harder or more harmoniously. The energy of our Chairman was most infectious and not infrequently he required us to meet more than once a week In due course two reports were drawn up They are very thorough and deal not only with the question of adequate protection for the operator, but with such important questions as working hours, holidays, fresh air, ventilation and construction of X ray rooms The introduction to the report reads as follows —

"The danger of over-exposure to X rays and radium can be avoided by the provision of efficient protection and suitable working conditions"

At first, there was consternation among the manufacturers, for this country was the first to insist upon the need for protection—that is to say, protection based upon experiment and reasonably adequate The manufacturers had their working designs which were totally inadequate for the additional weight of protective material demanded Without a moment's hesitation, as though infected by the spirit of the committee, they scrapped their designs, brought out new forms of apparatus, in every respect up to the standard set up by the committee and the tests of the National Physical Laboratory In no other country would such a thing have been possible without definite legislation The Ministry of Health, too, took up the matter and wherever it had control or could exercise persuasion, the standard set up by the committee was ordered or advised It is doubtful if to-day you could buy any apparatus in this country, at any rate of British manufacture, that does not bear the imprimatur of the committee

Finally, the Home Office invited us to express an opinion on the question of including certain diseases and injuries in the Schedule under the Workmen's Compensation Act, 1906

Russia has quite recently passed some very stringent laws for the protection of X ray workers These regulations are issued under the authority of the Commissariat of Labour and deal with hours of work, which are limited to four hours a day, and also lay down definite rules much on the lines of our committee, but they require each worker to be given at least six weeks' holiday a year, preferably in two halves They provide also for systematic medical inspection of all X ray workers

Some New Facts

In conclusion, I would ask you to look at some few facts which I have been able to bring forward as evidence of the *immediate result of protection* The following have been given to me by Dr Mottram —

1 Lymphocyte count of the staff of the Radium Institute in 1919 gives an average of 1697 compared with an average count of a number of controls of 2751

2 Polymorph count also of the staff of the Radium Institute in 1919 Here again the average of the staff was 2991, compared with the average of the controls which was 6162 In both cases the controls were taken from the *Journal of Experimental Medicine.*

3 White blood count of the staff of the Radium Institute *after increased protection*, which began in 1919 This table gives a count of total white cells in thousands per c mm In 1919 the average was 4000, and it steadily rose until in 1926 it reached the steady figure of nearly 7000

Prof Russ has lent me a chart recording systematic red and white count of two members of the staff employed at the Middlesex Hospital in the radium department They have been remarkably steady for some years

I have received a number of letters regarding the question which we are discussing to-day —

Mr Cecil Rowntree, whose Hunterian lecture at the Royal College of Surgeons in 1909 was on the subject of X ray carcinoma, writes "I think it would be quite right to say that we need not anticipate further cases, having regard to the fact that burns and dermatitis are now practically unknown"

Dr Mottram is even more definite "Anyone who burns himself nowadays in the handling of radium is a suicide, and as such he ought to be dealt with under this clause in his policy" Dr Kaye writes that he is quite convinced that, providing the recommendations of the committee are obeyed, the risk to the operator is absolutely negligible from the physical standpoint at least He makes the following significant remark "It is difficult to do anything for the fool who calmly lights a cigar while sitting on a gunpowder barrel" Dr Gilbert Scott, in sending me the statement of Dr L. Ash, who systematically makes blood counts on the X ray staff of the London Hospital, states that so far as the total blood cells (red and white) and the differential counts are concerned, there is no change of importance in the present as compared with previous years

I have now put to you the position as far as my own knowledge and investigation allow me I am convinced in my own mind that the very earliest indication of undue irradiation is shown in the state of the blood, and that this should be made the basis of investigation in any proposal for life insurance Naturally, one who already has a definite dermatitis, with the possible risk of skin carcinoma, is not a fair risk, though there are very many people who have on the hands X ray warts from exposure years previously, but who, under present day protection, are fit and well and have no extension of the trouble, they have learned their lesson

THE HYGIENE OF TRAMP STEAMERS

FOR his presidential address to the Services Group of the Society of Medical Officers of Health, on Jan 27th, Dr J Howard-Jones, M O H of Newport (Mon.), took as his subject, Sanitation in the Merchant Marine, limiting himself to the tramp steamers of 300 tons and upwards Sanitation afloat was, he said, hampered by the division of responsibility, the port medical officers were responsible when the ship was in use, but the Board of Trade, though it had no doctor on its staff, passed the plans, and it was consequently difficult for the medical officer to get carried out on new ships the alterations that were necessary to provide good ventilation or other needed hygienic requirement The seamen of some foreign, especially Scandinavian, nations had by law better accommodation than had British seamen, so ships sold to those nations or to some of our colonies had to be pulled to pieces and the crew accommodation enlarged before they were allowed to go to sea under their new flags We had lost our pride of place as showing the world the best hygiene there was in ships For the dirty conditions on board the men were themselves responsible At the close of his address an informal conversation arose, in which the Board of Trade was criticised by some, but Dr W M Willoughby, speaking for the Port of London thought the Board had done well, in this present time of unemployed seamen, in causing as little expense as possible to ship owners Dr A Elder was satisfied with the action of the Board, which had adopted, without delay, all the improvements he had asked for in his book He thought men were less clean than before the war, they did not use baths when these were available, not even when hot water was supplied Differing from Dr Willoughby, he thought firemen kept their quarters cleaner than sailors Fleet-Surgeon W E Home said that, thanks to the work of Dr. Howard-Jones and his associates in the last 20 years, seamen were now housed much better than formerly, as he had had recent occasion to observe The men must learn to keep their quarters clean, he had never seen such a heavy infection with bugs as in a ship recently It was stated by an Australian doctor present that 120 cub ft, the statutory cubic space per man, covered in England both sleeping and living accommodation for the men (mess-room, bath room, &c), but the whole 140 cub ft for Australian seamen must be given to their sleeping quarters Prof H R Kenwood remarked that if things were as reported in that room the Board of Trade did not appear to realise that good hygiene paid It was desirable to convince the Board, and he sketched how this might be done Dr Andrew Balfour asked how it was that other countries had gone ahead in their regulations Was it that their men would not go to sea in bad hygienic conditions? No one provided an answer to this question, but it was suggested that bad hygiene and dirt kept good men away from the sea, and that the want of these good men lowered the average self-respect Fines may be imposed on seamen by the captain of a ship for keeping crew spaces dirty, but the Board of Trade, so it was stated by Dr Howard-Jones, discourages insistence on these fines

At the end of last week an outspoken debate on the question of seamen's working hours took place at the International Labour Office at Geneva Wide difference was expressed as to the need or expediency of making international regulations, but it is clear that sailors' organisations are alive to the necessity for ensuring that the conditions of service should be improved

Webster's Test for T N T in Urine —We have been asked to state that the discoverer of this test was not the late Mr John Webster

---

SHEFFIELD HOSPITALS AND THE COAL STRIKE —It was stated at the annual meeting of the Sheffield Hospital Fund Committee that the seven months' coal stoppage had resulted in a fall of £19,500 in the revenues of the Sheffield hospitals

Personal Observations
UPON THE
CLINICAL FEATURES OF POLIOMYELITIS.

An Address delivered before the Medical Officers of Schools Association on Feb 4th, 1927,

BY JAMES COLLIER, M D , F R C P LOND ,
PHYSICIAN TO ST GEORGE'S AND THE NATIONAL HOSPITAL, QUEEN-SQUARE

IT has been intimated to me that it would be as well for me to deal chiefly with the clinical aspect of this malady and I think the suggestion was wise; for a clinical observation well recorded always stands the test of time Nothing ever upsets it or makes it wrong It never leads us astray And every one of us, however little opportunity we may have had for observing this disease, may, from the observation of a single case or a few cases, make a record of a hitherto unobserved fact with an important bearing Upon the pathological aspect of this disease there is little that I could tell you which is not available to you in modern text-books There is an admirable summary in the Lumleian Lectures for 1916 by the late Dr F E. Batten, and since this work was published little except further confirmation of the views therein contained has been added, except the separation of the cases of the then undescribed "lethargic encephalitis," a few of which had crept into the cases described by Batten as cases of poliomyelitis The epidemiological and public health aspect of the malady bristles with difficulty and potential danger, with ignorance and paradoxes

DEVELOPING KNOWLEDGE OF THE DISEASE

When I first entered upon medical studies 40 years ago there was no suggestion that poliomyelitis was an infectious disease Twenty-two years ago Wickman proved that it was infectious by human contact only, and I think that his proof remains unshaken Now some of us think that poliomyelitis is not infectious so far as case to case infection is concerned, and that the future is likely to prove *that only* recent carriers can spread the disease There are many known facts and one has to marshal these epidemiological facts into some sort of working order One has, in fact, to make an hypothesis which will best fit in with the facts, and in so doing I have no doubt that the truth gets squeezed and distorted a bit and we are apt to turn a blind eye upon an obvious truth which does not fit in with the hypothesis But such an hypothesis, though most necessary and useful for the working moment, is apt to melt into thin air at the touch of a little more knowledge

We know well what poliomyelitis has done in the past, but who can say what it may do in the future? Will it disappear silently while we sleep and suddenly as chlorosis did all of one day from London Town where it had been endemic for centuries? Or will it treat us to an American epidemic? I suggest to you that it is not likely to play terrible havoc, unless it disappear first of all For we always have poliomyelitis in London every month of every year and are therefrom, I submit, a "salted" community Which of us who gained our knowledge of poliomyelitis long ago would have then believed it possible that in one relatively small district of the world 50,000 cases could have occurred in the space of a few years, culminating with some 20,000 cases, 5000 deaths, and 12,000 cases of paralysis in one autumn, in New York State in 1916, or that, in one small and isolated village in the west of England with a total population of 119 souls, 45 were seized with poliomyelitis in the space of a few days, every house having its two, three, or four victims—two of them being 16 years of age? This was in the Cornwall and Devon outbreak of 1910 Every form of the disease was seen in that village in that week I will ask you now to contrast this outbreak in Stoke Rivers village with another outbreak which occurred in the same year in the highly populous town of Edinburgh There were, I think, 62 cases all of the usual spinal type There were no abortive cases. No two cases occurred in any one family or in any one street Case contact or family contact could be absolutely excluded in all but three of the cases. Headache only occurred in six of the 62 cases The contrast is very striking Forty-five cases out of 119 people with every type of the disease in the one case with clear contact in every case; and 62 cases in 420,000 with *one type of the disease and with* contact absolutely disproved in nearly all the cases in the other These two epidemics were reported on the same evening before the Epidemiological Section of the Royal Society of Medicine and the attitude of the audience was very different to the two reporters. They patted the Devon and Cornwall man on the back and said his was excellent work Certainly he had a very inspiring experience and had managed to get the help of Levaditi in Paris and had the virus of his epidemic proved. Moreover, the little village outbreak to which I have referred was only one of many local outbreaks which he was able to observe But the audience were positively rude to the Edinburgh man. They said his report was not worth listening to, and that from an epidemiological point of view it was of little value, and even suggested, I think, that if he had had the capacity of looking properly, he would *have found abortive cases and would have done* more successful tracing. I suggest to you that both these reports *were of the highest interest as examples* —the one of poliomyelitis running riot in a susceptible community following a carrier epidemic; the other of poliomyelitis, epidemic upon a highly salted community with multitudinous carriers I have put them before you to impress you as strongly as I can of the vagaries and possibilities of this disease and to hint at a possible explanation

THE CEREBRO-SPINAL FLUID

Dr J G Greenfield, our distinguished pathologist at Queen-square, will tell you that he will put us right about the diagnosis of poliomyelitis in the acute stage from his examination of the cerebro-spinal fluid in 100 per cent of our cases I think 98 per cent would be a more just estimate Lumbar punture is therefore a most helpful measure in making a correct diagnosis of poliomyelitis from the earliest appearance of the symptoms until several days after pyrexia has disappeared It is also often a dramatic means of removing, and permanently *removing*, some of the most distressing symptoms such as the headache and head retraction and the bodily pains and sometimes it seems to relieve the pyrexia immediately. Whether its performance and repetition have any effect in lessening the severity of resulting paralysis or averting death I cannot say, but what I can say is that it does no harm and can always be performed without any distress to the patient whatsoever, if a fine hypodermic needle and a few drops of 2 per cent novocaine solution are previously employed

Just now and again lumbar puncture fails you in the diagnosis of poliomyelitis May I give you the bare details of two such happenings which have occurred to me recently

The first was that of a lad, returned from public school as a contact Forty-eight hours after leaving school and when playing golf he was seized with a severe headache. I saw him that evening with a temperature, a *pink skin and* headache, nystagmus and head retraction, and with the right abdominal reflexes and the deep reflexes of the legs absent The lumbar puncture gave a completely negative result The M O H was notified by the doctor before we knew about the C S F The M O H subsequently pressed me to certify this case personally as it concerned a public controversy The patient was by this time apyrexial and convalescent, and I was in a bit of a tight place *for an* absolute proof of my diagnosis, so I did another lumbar puncture and found the C S F quite typical of poliomyelitis.

Do not let this case lead you to suppose that the fluid when normal early on always becomes diagnostic later. Here is the disproof —

I saw recently a little girl on the fourth day of her illness with the pyrexia almost gone and practically convalescent I pronounced this case to be a typical abortive case The cerebro-spinal fluid was absolutely normal But her brother, who was in the same house at the time, subsequently went down to the paralytic form of the disease

These are the only two cases that I have seen in which the cerebro-spinal fluid has been even temporarily normal The characteristics of the cerebro-spinal fluid in poliomyelitis are that the albumin-content is increased and that it contains cells in excess with normal sugar and normal chlorides and that it is sterile on culture But whether the cells are lymphocytes or polymorphonuclears or mixed or in what numbers they exist does not seem to have any relation to the type of the disease or to its severity or to the prognosis My pathologist reports "this fluid is indicative of a very severe infection," and the case turns out a mild one and completely recovers. Or he reports "a mild infection" and a fatal issue ensues forthwith I think that when all the cells are found degenerate the result is usually very favourable

CLINICAL PICTURES

Wickman, among his 1500 cases in the Swedish epidemic of 1905, described the clinical pictures of these patients under the following names the carrier; the abortive case, the neuritic case; the spinal case, the spreading spinal case (ascending or descending or both), the meningeal case, the brain-stem case, the cerebellar case, the cerebral case, the mixed case

This classification of Wickman's has been sneered at as neither a clinical nor a pathological classification and therefore unscientific, but it is nevertheless a most useful aid to memory and thought. One sees all these types and no one has as yet made a better classification I will explain to you presently three other types which I think are worthy of emphasis, and will now say a few words about each of these types

The Carrier

The carrier is not a hypothetical individual for he has been caught and caged after infecting others, and his virus obtained, cultured, and a chain of monkeys infected from this with typical clinical and pathological results Sometimes this carrier himself succumbs to the disease as did Taylor and Amos's carrier In this respect poliomyelitis is like meningococcal meningitis where 4 per cent of the carriers succumb But it seems probable that in poliomyelitis far fewer of the carriers are invaded All the carriers seem to gain immunity I think that the carrier is much more virulent as soon as he begins to carry and that his virulence thereafter wanes and dies out in a comparatively few days Perhaps it is the carrier alone who infects, and certainly it is a chain of carriers who perpetuate the disease and carry it over from season to season and give rise now and then to the sporadic cases of the disease which occur in London, for example, every week of every year His virulence is also dependent upon contact with high susceptibles and he is probably an important agent in "salting" the community

Carriers are probably much more numerous than cases of poliomyelitis Kling, Pettersen, and Wernstedt examined six families in each of which there was one case only and found 18 carriers among the non-affected members—a proportion of three to one

It may be of interest to tell you a good story of a carrier

A farmer in the West Country sold a horse to another farmer at a market town, and according to custom delivered the horse at the farm of the purchaser some 15 miles away a day or two later He left home with his child ill with poliomyelitis Having delivered the horse he took a meal with the purchaser and sat at table between two children Within 48 hours both these children were ill with poliomyelitis and within 72 hours their mother and another child were infected This farmer was surely the carrier who had infected his own child

The question of a carrier is sometimes of prognostic importance, as in the following example —

I was called in August last by Dr H Fraser of Harpenden to see three children of one mother all very ill with poliomyelitis and still pyrexial There had been no cases in Harpenden before these occurred, nor were there any afterwards In reply to the mother's question of distress as to whether her other child in the house would take the disease, I said certainly not Immune, when all the others went down, this child was very likely the carrier

The Abortive Case

The case that I am about to describe to you is typical of nearly all those which I have seen in the present epidemic period I am taking as abortive cases only those which show definite involvement of the nervous system I have seen a great many abortive cases I well remember having it myself at the age of 9 years and shall never forget the "machine gun" headache and stiff neck nor what my miserable limbs felt like after I remember my sister having it in our nursery at home and the consternation of us children that for days she could not stand upon her legs I remember my son having it and my physicians cheering me by diagnosing tuberculous meningitis

A boy was removed from an infected school at Broadstairs by his parents and brought to London I saw him the following day looking the picture of health and eating heartily Twelve hours later the temperature rose and remained 99 5°–100 5° F. for 24 hours, the boy feeling as well as possible, eating heartily and with no catarrh, throat, or discomfort Then his head began to ache violently, the worst headache he had ever had I saw him within two hours of the commencement of the headache The temperature was 104° He was then very pink—almost pink enough to suggest scarlet fever, but pink all over and without any puncta He lay with head retracted and neck stiff, and any attempt to flex the neck gave him severe pain in the spine down to the sacrum Kernig's sign was well marked He said he felt quite well but for the headache There was very marked nystagmus The pupils were unequal and the right one, which was the larger, reacted badly When he held his hands up they showed conspicuous little jerky movements of fingers and joints which he could not control and which are very characteristic of the disease The abdominal reflexes were absent, as were also the deep reflexes in the arms His breath smelt peculiarly nasty I drained off all the cerebro-spinal fluid I could get—some 2 ounces It was typical of the disease The drainage instantly relieved his headache which did not return It also relieved his head retraction He was quite convalescent three days later with the disappearance of all his physical signs, but for a few days he said that he could get no push into his muscles

Nearly all the abortive cases that I have seen have been just like this one with pyrexia, headache, signs of meningeal irritation, nystagmus, jerks of the limbs, and some loss of reflex action superficial or deep, and occasionally some loss of power Other signs met with have been catarrh of nose and throat vomiting, diplopia, and convulsion I have not met with the profuse sweating nor the severe diarrhœa which have been prominent in other epidemics Doubtless there are much milder types of the abortive form than that I have just described to you, and in the severe epidemics Wickman and other workers have proved cases of mild fever without any nervous signs at all to be cases of poliomyelitis If such cases occurred at Broadstairs they were very rare Perhaps I saw one at Broadstairs but I did no lumbar puncture and disregarded it

The Spinal Case

The spinal type of the disease in its usual form is so well known to you as to make description superfluous I need hardly emphasise the frequently occurring cases where the thoracic spinal cord is solely or chiefly implicated, giving rise in the end to spinal curvature This disease is by far the commonest cause of scoliosis and kyphosis and is often overlooked as a cause for these conditions But there are several peculiar varieties of the spinal type which deserve special mention Here is one of them

More than 30 years ago a man aged 22 years was admitted into the National Hospital under Dr Thomas Buzzard, pyrexial and completely paralysed in all four limbs and in the lower trunk There was no affection of sensibility nor of sphincters The diagnosis of poliomyelitis was obvious I found that all his reflexes, both superficial and deep, were present, and I was greatly surprised and communicated my surprise to Dr Buzzard who at once said, "You will find that this patient will make a complete and dramatic recovery" This patient did make a rapid and complete recovery

This autumn Dr F H Watson sent me to St George's Hospital a child from Sheerness paralysed in all four limbs with poliomyelitis, saying that he was tired of hopeless cases of this disease and would I relieve him for a time of this one I found notwithstanding the paralysis of five days' duration, that all the reflex action, both superficial and deep, was present I said to my students, "this child will recover rapidly and completely," and notwithstanding great disbelief on their part, we returned this child to Dr Watson in four weeks perfectly well, having brought about this miracle by doing nothing except a lumbar puncture to confirm the diagnosis

Such cases as this with retention of all reflex action always do recover perfectly and rapidly It is important that you should know this, though it will worry you in your accepted notion of the pathology of the disease But you must not think that from what I have said recovery does not occur when the reflexes are lost It often does sometimes completely. sometimes partially

Another unusual spinal type which may puzzle you is that of acute transverse myelitis I can make this plain to you in a very few words Imagine a severe local dose of poliomyelitis virus delivered from the intestines along the ninth dorsal nerves into the small dense ninth dorsal segment, where there is little grey substance to matter The result is intense inflammation with swelling of the segment so great as to compress all the tracts and abrogate all function below the level of the lesion with paralysis of motion, sensation, and sphincters, below the umbilicus But the paralysis is not for long a flaccid one It soon becomes spastic with extensor responses and increased reflexes It usually makes good recovery when the swelling abates Rarely it leaves complete transverse destruction of the spinal cord Here is a good example I was called by Dr T Gardner in October last to see a lady at Brighton She had been to a dance on a Saturday, where she met her carrier On Monday she was seized with the most severe headache of her life On Wednesday morning she woke having lost all power and feeling in the legs and with complete retention of urine She had the common meningeal signs of the disease, with those of a transverse lesion of the cord The cerebro-spinal fluid was typical She was obviously regaining sensibility when I saw her a few hours later, and therefore I made a very cheerful prognosis which has been justified

The Neuritic Case

The *neuritic type* of poliomyelitis is nothing more than some variety of the spinal type in which there is great pain and tenderness in the *paralysed region* Sometimes the pain and tenderness is so great as to increase the apparent paralysis to completeness It is a most fascinating variety of the disease from the pathological view It does not seem to make a very bad prognosis, nor to occur with the completely paralysing varieties of the disease The muscles are as tender to pressure as those of an alcoholic neuritis, hence the name neuritic type," *any attempt at* stretching the affected muscles by passive movement produces agony Some of us think the joints are also inflamed Contracture of an early kind is likely to follow this type and the more so because you cannot splint or stretch because of *the pain* This neuritic type is sometimes troublesome in diagnosis I have many times been called to cases of acute rheumatism as cases of poliomyelitis because of the apparent paralysis that the pain may cause and vice versa, but you will remember that pain always increases the reflexes both superficial and deep whereas poliomyelitis generally abolishes them The following case of difficulty may interest you in this connexion

I was called recently by Dr De Vere Hodge, the M O H at Woodford, to see a case notified as poliomyelitis in an institution containing several hundred boys A boy three weeks convalescent from poliomyelitis had recently been admitted and had slept for some days in the same room as the patient The patient had been taken ill a few days before with severe diarrhœa with copious watery evacuation lasting 12 hours There had been no pyrexia and no headache Next morning he had bad cramp *in the legs followed* by continuous severe pain in all four limbs with extreme tenderness and pain on stretching His arms had recovered when I saw him, but his legs he could not move. All the reflexes were increased, and the agony I gave him in obtaining these brisk reflexes was obvious reason why he could not move this legs

Now here was a difficult case for the doctor in *charge A contact* with an undoubted case of poliomyelitis Apyrexial cases of poliomyelitis certainly do occur. Diarrhœa at the onset is in all the books as a well-known occurrence in the disease The tenderness, pain, and agony on passive movement were exactly like what one sees in poliomyelitis No wonder the medical officer notified the case However directly I had examined this case, and before the cerebro-spinal fluid had been examined, I turned this case down as certainly not a case of poliomyelitis, on these grounds I am an utter agnostic of case-to-case infection in this disease and even for a believer if such a person exists the period was much too long Apyrexial poliomyelitis bids you be very sure before you make a diagnosis Severe gastro-intestinal upset may cause acute tetany and a host of other queer muscular troubles. I have never seen cramp in poliomyelitis, nor the *reflexes* universally brisk The cerebro-spinal fluid proved normal in this case

There is one suggestion I wish to make with regard to children who are brought to you with the complaint that they have gone weak on the legs and fall unduly and are *unwilling to walk You find a healthy child* with no physical signs and cannot explain the condition Such children always recover in a little time I have seen this condition succeed definite abortive poliomyelitis so many times as allow me to suggest that this is a reasonable cause in all the cases I have one of the Broadstairs boys under my care at present who was an abortive case, and for a long time went lame on one leg when he got tired Yet never could I find the least trace of weakness in any muscle

The Spreading Spinal Case

The spreading cases are of the Landry type, ascending or descending, or both. Usually in poliomyelitis when you are called to a case after the spinal paralysis has developed you are able to say with certainty that the worst is over and that nothing but improvement will subsequently follow. But before you do this make quite certain that the paralysis is stationary Ask the patient how the weakness compares with what it was two or four hours ago, or wait some hours with the patient and see for yourself Otherwise an innocent-looking lower limb paralysis may creep up and involve trunk, arms, and respiration and prove fatal I have never seen it spread when once it has remained the same for hours It spreads rapidly sometimes the increase is obvious from minute to minute I remember spending the night with Dr F S Lloyd, of Luton watching the paralysis spread from the legs to the trunk and then to the intercostals and arms Then the diaphragm failed and for nearly an hour he breathed with his neck muscles Then we noticed the diaphragm come in again and then the intercostals, and before we left him we were safe as regards death This patient made a complete recovery The *spreading* cases seem to be peculiar to some seasons I have not seen a single case during 1926 In the autumn of 1924 nearly every case I saw was of this type and almost all of them were fatal

The Meningitic Case

You will say at once that I have already described the meningitic form of the disease in dealing with the usual abortive case in which the signs are so largely those of meningitis So I have, and this is what I take it most of the epidemic observers have called the meningitic type. But the following case will tell you of something much more startling and something which was entirely new to me.

It was a case of Dr M O. Raven's at Broadstairs—a boy who had come home from school five days before with a bad headache and a temperature He soon developed diplopia and head retraction. When I saw him his temperature was low He was deeply unconscious with the eyes open and with complete incontinence He was very thin, white, with retracted abdomen, and stiff extended legs with increased jerks everywhere and extensor responses A typical picture of a dying tuberculous meningitis I said to Dr Raven that I was sure it was tuberculous meningitis I said to the boy's mother "I do not think that your boy has the disease which is about the town, I fear that it is another much more fatal disease, and if it is, I can give you no hope, but if it is the disease that is about the town I think he will get better." So sure was I that he would die of tuberculous meningitis that I made the alternative prognosis rosy to comfort the woman. I took the C S F back with me with the following result chlorides normal, therefore it was not tuberculous meningitis, sugar normal, therefore it was not any form of bacterial meningitis, culture sterile and fluid characteristic of poliomyelitis This lad made a rapid and nearly complete recovery, and a fortnight later was well but for a slight weakness of one deltoid

In this case I had unexpected and entirely undeserved luck in prognosis

The Brain-stem Case.

This type of case I leave undescribed because I have never seen one, and because I am unconvinced by any descriptions of such a condition which have been made I know that lethargic encephalitis loves the brain-stem and basal ganglia, and it is obvious that the cases of brain-stem poliomyelitis which Batten published in the Lumleian lectures of 1916 were examples of lethargic encephalitis which was, at that time, an undescribed disease You surely would not have me describe the nystagmus, diplopia, pupil changes and peripheral facial paralysis of poliomyelitis as a " brain-stem " type, since they are met with as transient symptoms in any type of the disease and are important in diagnosis only They are, of course, indicative of a mild involvement of the brain-stem Such symptoms do not seem to be on the same footing as the limb paralysis, they always get better Moreover, the facial paralysis sometimes involves loss of taste and therefore cannot be due to a nuclear lesion It is interesting to read that ordinary Bell's paralysis is much more prevalent when an epidemic of poliomyelitis is incident, but on this subject I have no knowledge

The Cerebellar Case

This is strikingly unlike the other forms of the disease It is a matter of an acute onset of cerebellar ataxy following headache and pyrexia The following case was a beautiful example '—

A public school-boy on returning from a walk fell out 200 yards from home saying that he could not get home because his head was so bad He was carried in and placed in a chair where he collapsed, not mentally but physically This was the flaccidity of acute cerebellar disease A diagnosis of a " touch of the sun " being made, he was carried to bed where he went to sleep Next morning no one could understand his speech, it was so wildly ataxic He could not sit up or guide his limbs, and he was sick when his head was moved He had only a slight temperature I found him with the most extensive nystagmus, speech ataxy and bilateral ataxy The C S F was typical of poliomyelitis I brought him back with me to London, and observed day by day an ever quickening disappearance of all his symptoms He was quite convalescent in six weeks

This will impress you with the very great recuperative powers of the cerebellum if the lesions are not too severe

The Cerebral Case

In this type severe and repeated convulsion usually follows upon pyrexia and headache, sometimes fatal in a very few hours as in the first fatal case at Broadstairs, sometimes lasting many hours or days, and merging into lengthy subcoma from which the patient gradually rouses to show some cerebral defect, mental, diplegic, hemiplegic or hemianopic, or perhaps to recover completely It is usually held to be the common case of hemiplegia in a child following convulsions. Sometimes the hemiplegia or other sign of cerebral involvement comes on very quietly even in the conscious state, as in a case which I saw with Dr W. Pitt-Payne of Bromley, who called me to see a boy with an obvious meningitis but who seemed so well and so little distressed by his illness that doubt had arisen as to what was the matter When I arrived I pointed out to Dr Pitt-Payne that the boy had a complete left hemiplegia The doctor was astonished for he had examined the boy some two hours previously and found no hemiplegia But there it was, a severe hemiplegia too It had come on in a perfectly conscious boy who was not feeling ill The cerebro-spinal fluid was typical and this case made a complete recovery.

The Relapsing Case

I must now refer, for a moment, to cases in which the patient seems to become apyrexial and convalescent, and after a few days redevelops symptoms sometimes of alarming severity It is a matter of a second blaze of infection which has remained alive within the tissues I think that you may perhaps anticipate the occurrence of a relapse by an unusually flat-topped temperature chart in the first few days, and by the fact that the so-called apyrexial interval contains little sudden jumps of temperature which suggest continued infection, instead of the usual rapid blaze, high peak, and rapid fall of temperature Now whatever the books may tell you about dreadful results in a relapse, I have never seen any harm occur, no occurrence of paralysis, and no increase of paralysis Indeed, in a case which I saw with Dr Pollock a short time ago with an eighth day relapse with very high fever and great restlessness and headache, it was obvious that the paralysed legs were improving continuously in spite of the relapse

The Mixed Case

It is amazing how rarely one sees a case of polio myelitis in which the types are mixed, and this is why for so many years the spinal, meningeal, cerebellar, and cerebral forms were described as separate diseases But the epidemics in which the several types are seen much more often, and the pathologists have settled that all these clinical pictures result from one and the same infection I suppose the explanation may be the curious local advent of the virus to the nervous system from the mucous membranes by way of the nerves only, as in rabies and tetanus, and the rapidly acquired immunity which may keep the disease local But one does see mixed cases Some years ago a little girl was admitted into St George's Hospital, under my colleague Dr J A Torrens, with right hemiplegia, atrophic paralysis of the left leg, and peripheral facial palsy of the left face Here were the spinal, cerebral, and brain-stem types altogether

As my last clinical example let me describe to you a case that might be justly called one of general poliomyelitis

A man belonging to London, aged 26 years, was admitted under my care at St George's a few weeks ago with the story that on the Tuesday of a certain week he developed a bad cold and felt ill On the Thursday he felt better and returned to work, but developed diplopia for which he sought his doctor on Sunday morning The doctor, finding him pyrexial and with diplopia, sent him to hospital where he gave a detailed and accurate account of his illness, during Sunday night he lapsed into unconsciousness, and on Monday I could find nothing alive at all in his nervous system except miserable attempts at respiration Consciousness, pupil reactions, swallowing, coughing, reflexes, sphincters—everything gone The whole nervous system killed out quietly in 24 hours He had a large patch of pneumonia by this time The cerebro spinal fluid showed a high polymorph count, so we thought of acute pneumococcal meningitis as a well-known rapid destroyer But the cultures were sterile Lethargic encephalitis was mentioned, but was impossible for no polymorph has ever been found in the cerebro spinal fluid in that disease Moreover, I have never seen lethargic encephalitis knock the spinal cord out as a whole My pathologist at the autopsy found the whole nervous system bright scarlet in colour, and said at once lethargic encephalitis I said "no," this is poliomyelitis The sections subsequently showed an acute inflammation of the whole central nervous system, and in the perivascular lymphocytic exudation of that inflammation were the multitudinous polymorph cells which are characteristic of poliomyelitis and which alone distinguish it from the inflammation of lethargic encephalitis and the inflammation of syphilis

This was the most severe case of poliomyelitis that I have ever seen or heard of.

The Apyrexial Case

One word with regard to cases which show no pyrexia or headache and are therefore difficult for the doctor, for I have one at the present time, paralysed in the legs, which occurred at Broadstairs last July though it was not notified, and which seemed to me to show that the Broadstairs epidemic did not come from Brittany as many supposed when it appeared in October, but that it came from Broadstairs The apyrexial cases without headache are rare in my experience. I believe that they only occur in sporadic cases, and mean infection in a partially protected subject They do not occur in the epidemics They are always of the pure spinal type like most of the sporadic cases They seem to be much less common of recent years, for Allen Starr, writing of a large number of cases years ago, says that 30 per cent of them were apyrexial, whereas I have certainly not seen half a dozen apyrexial cases in my life. One has to remember that poliomyelitis is certainly increasing in virulence Allen Starr did most of his work before epidemics of the disease were common, and I have had experience of a considerable epidemic period

Rashes

A great many rashes have been described in poliomyelitis, none of them very usual I am not here referring to the pink skin upon which I have laid some stress as a rash But there are two rashes which are worthy of mention One of these is herpes zoster, which has been reported many times It is what one would expect, for I cannot believe that the inflammatory lesion of poliomyelitis never invades the roots and the root ganglia I think that there is strong clinical evidence that it does in some cases, as, for example, those with peripheral facial palsy with loss of taste But I personally have never seen it nor have I seen the scars of zoster on any old case of infantile paralysis that I can remember The other is a striking rash of most peculiar appearance and distribution consisting of large bluish-purple papules, not collected in bunches and distributed over the paralysed region only I have seen this rash quite half a dozen times The first time I saw it was years ago in a nurse at the Hither Green Fever Hospital, who was pyrexial with a severe paralysis of the right arm and shoulder which upper limb and shoulder were smothered with the papules I have described The last time I saw it was the other day at Harrow with Dr S H. A Lambert and Dr. C F Mayne in a fatal case of paralysis commencing in and chiefly affecting the whole trunk The whole back and sides were covered with a similar rash which had been attributed to the use of a liniment for pain You may say this was herpes zoster and perhaps it was a rash of the same pathogeny Yet though I know and have seen that herpes zoster may look like anything from an erythema or a purpura, or a papular rash to the fully developed lesion, yet it has always had a characteristic corymb-like distribution in patches, and that has not been the case with the eruption which I have just described

SOME DEDUCTIONS

I hope I have not wearied you with much clinical detail but it is important and upon it has been based most of our knowledge of the disease and all the inspiration which Wickman brought to his pathologists and which led to the sound bacteriological and pathological understanding which we have of poliomyelitis One word of comfort to you as medical officers in charge of schools This disease does not like schools, institutions, and large towns It has been said that it will not spread in institutions In one of the bad epidemics in America during a raging season, 45 schools of the infected locality containing 3600 children of the most susceptible age were kept under observation and only one case occurred At the Hospital for Sick Children where pyrexial cases of poliomyelitis are often received, no case has been recorded of spread of the infection to another child Dr. Batten, who had a 30 years' experience of Great Ormond-street Hospital went into that point with his characteristic thoroughness and vouches for the fact Let any one of you who holds to case-to-case infection in this disease explain such a fact Take what happened at Broadstairs in the schools, all the many cases occurring in the blaze of a few days and then no more cases. There was no case-to-case infection Look at the results in the Broadstairs preparatory schools as compared with what was happening in the town True we had two fatal cases before the malady was discovered, and one in a lad who was immediately removed by his parents to the depths of the country Otherwise one trivial case of slight paralysis was the only bad result. There were plenty of cases of bad paralysis in the town This was because poliomyelitis does not like schools and will not be virulent in schools

May I commend to your notice who are especially interested in community infection, epidemics and disease to the fascinating work of W W C. Topley and M Greenwood upon community disease in rats[2] and the exhilarating work of Surgeon-Commander S F Dudley on invasion,[3] carriage, and salting which has just been published by the Medical Research Council, both of which will help you much in the understanding of epidemic disease

The work of Topley and Greenwood has been carried out with infectious diseases in communities of rats They draw these conclusions.—

(1) If you keep a herd of infected rats strictly isolated you will in time perhaps in a short time, get rid of the infection

(2) But if you allow a few unsalted immigrants to dribble into the infected herd from time to time you will never get rid of the infection

(3) The effect of every addition of susceptibles is to raise the virulence of the infection, and in time the hitherto immune members of the herd succumb and at last even those who have recovered from the original infection succumb to the ever-increasing power of the infection

(4) It is a much safer thing for the herd to introduce a thousand susceptibles in one day than to introduce ten a day for a hundred days, for the obvious reason of the ever-rising virulence which repeated ingress causes

From these conclusions it would follow that we should keep our infected communities together and allow no ingress if we wish to break a community epidemic.

Surgeon-Commander Dudley's work has been done upon humans in schools and depôts and he has reached the same conclusions He says: If any one of us is exposed to an infection emanating from the respiratory passages—he calls it "droplet" infection—one of three things must happen: (1) we become invaded and develop the disease or (2) we become carriers of the disease or (3, we become "salted" or immune to the disease Which result will happen will depend. Dudley argues upon three variable factors first, the amount of infective material received by the host per unit of time second, the rate at which the infective material can be destroyed by the host: third, the rate at which the microbic proteins stimulate or depress the immunity mechanism of the host. These factors being equal the result will depend upon the distance of a susceptible host from a distributor of infection as to whether the former becomes a case, a carrier, or immune

There is another important factor in the wax and wane of a community infection and that is bacterial variation in response to changes in the herd immunity, and this will explain the dying out of a community infection despite increasing numbers of carriers and despite the continual introduction of fresh susceptibles as happened at the Greenwich Naval School with a diphtheria outbreak Dudley thinks that carriers acting in a suitable environment may prevent great disease outbreaks by supplying sub-infective doses to the more susceptible members of a population, and in this way the general resistance to epidemic disease is increased and the herd is vaccinated by its carriers This work has possibly a most important bearing upon poliomyelitis, for we know well that an epidemic of this disease in a community clears out all the susceptibles and leaves the community immune When another epidemic affects that community only those born after the previous epidemic are affected It seems to me that Dudley has suggested a likely explanation of the means by which this immunity is attained

An Address

ON

POLIOMYELITIS.

Opening a Discussion held at the Medical Society of London on Feb 7th

BY F M R WALSHE, MD, DSc, FRCP LOND,

PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN SQUARE, AND IN CHARGE OF NEUROLOGICAL DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL

ALL those of us who have had to deal with cases of acute poliomyelitis will have learned to regard seriously a disease which lays upon us such heavy responsibilities Not only have we difficulties of early diagnosis to contend with, and questions of treatment in which each case presents its own special problems, but there arise urgent questions of public health in the dealing with which there are no generalisations upon which we may safely rely There is certainly no acute specific fever in which the patient is so profoundly dependent for the degree of his restoration to activity upon the unremitting and skilled attention of his physician for months or even years after the short-lived infection has burnt itself out

In my brief contribution to the discussion which it is my privilege to open, it is manifestly impossible to deal with every aspect of the malady, and I need not apologise therefore for inevitable gaps in my remarks I shall content myself with an attempt to give a clinical conception of poliomyelitis as a whole, to indicate the lines of treatment of its various phases, and to summarise what is best established in respect of its epidemiology

THE CLINICAL PICTURE

In acute poliomyelitis we have an acute specific fever, a systemic infection, which may or may not proceed to invasion of the nervous system by the virus responsible It occurs sporadically and epidemically The complete clinical expression of the disease consists in a short-lived initial phase of constitutional disturbance followed by signs of invasion of the subarachnoid space and by those of involvement of the nervous tissue itself It is in the last that the specific lesion of the disease is produced But as long as 20 years ago the conclusion was reached by the Swedish observers of the disease in its epidemic form that an appreciable proportion of patients recover from the infection without developing paralysis, a conclusion which more recent investigations in America has amply confirmed, and G Draper may be taken to express the general view when he states that these so-called "abortive" cases may number from 50 per cent upwards of the total case incidence in any given epidemic We are in a position to say that these conveniently, if somewhat loosely termed, "abortive cases" depend for their occurrence upon the dying-out of the infection, either on the completion of the phase of general infection, or even after invasion of the subarachnoid space, but before the virus has gained access to the neuraxis itself

It is customary to speak of poliomyelitis as presenting two clinical phases, one of general and a subsequent one of nervous system involvement I submit, however, that a more precise as well as a more practical conception of the malady is obtained by recognising the existence of three clinically and pathologically distinct stages in its evolution one of general infection, one of invasion of the subarachnoid space and a third of invasion of the central nervous system itself It is only when the last occurs that paralysis ensues Each clinical phase has its corresponding pathological substratum During the general phase the virus obtains lodgment in the liver, spleen, lymphatic glands (and in the experimentally produced disease at least) in the bone-marrow, in all of which tissues lesions are found Secondly, the virus reaches the subarachnoid space by a channel to which we have to refer later, giving rise here to a characteristic meningeal reaction as revealed by examination of the cerebro-spinal fluid Finally, it may obtain lodgment in the grey matter of the central nervous system producing there the familiar inflammatory lesions

The study of the disease, therefore, in its epidemic form has served usefully to turn our attention from a too exclusive consideration of the ensuing paralyses to its preparalytic stages It is clear that if we could with certainty recognise and effectively scotch the infection at this period, we should deprive it of its terrors, since death when it occurs, like disablement, is the result not of general toxæmia but of nervous system involvement

The Phase of General Infection

Turning now to a brief consideration of the first of the preparalytic phases, that of general infection, we may say that it is very short-lived, lasting for from a few hours to three or four days The constitutional reaction may be so slight as to escape notice or may be of considerable briskness It does not as a rule present features by which we can identify it with certainty, although during the course of an epidemic the reaction may be of so uniform a quality as to allow the alert observer to suspect the character of the infection with which he is dealing Fever is the most constant component of the clinical picture, the temperature rising to 101° or 102° F The child suffers from malaise, and behaves in the manner customary with the febrile child Such local symptoms as develop appear to vary from epidemic to epidemic, and tend to conform to one of three main types a gastro-intestinal with vomiting and less frequently diarrhœa, a tonsillar with signs of faucial inflammation or a coryzal with symptoms of upper respiratory manifestation Whatever form the symptom-complex may take we may regard it as indicating the fully established general infection and not merely a prodromal stage Occurring in an uncomplicated form, this stage is free from symptoms of meningeal invasion, and the cerebro-spinal fluid is normal in character

The Stage of Subarachnoid or Meningeal Invasion

The onset of the stage of subarachnoid or meningeal invasion stands in a somewhat variable time relationship to that of general infection In certain severe cases the two phases may develop synchronously, or they may overlap, signs of meningeal invasion developing before those of general infection have abated, or finally, there may be a pause of from a few hours to a day or so between them When such a pause occurs, and while it endures, the child is generally assumed to have recovered from some trivial febrile disorder

Like the constitutional reaction, the meningeal reaction varies in intensity, being at times unnoticed at others of great violence. It is of even shorter duration, ending in recovery, or passing into the final phase of nervous tissue involvement within a few hours. The clinical components are fever, headache, pains in the back and limbs, rigidity of the spine with resistance to passive flexion, the so-called "spine sign" of American observers, muscular twitchings, and a peculiar starting jerky tremor when the patient is handled or makes voluntary movements. In severe reactions there may be head retraction, opisthotonos, and the combination of drowsiness with irritability, or even deep stupor. It is obvious that one or more of these components may be lacking in the individual case, but headache, the spine sign, and pain in the back and limbs we may regard as constant. During this phase examination of the cerebro-spinal fluid reveals the presence of a meningeal reaction. On lumbar puncture the fluid escapes under pressure, and is clear except when great excess of cells renders it opalescent. The cell content is constantly increased, the count ranging from 30 or 40 to 2000 cells per c mm. Early and very transiently polymorphonuclear cells predominate, giving place within a few hours to a lymphocytosis. As this change occurs the globulin content of the fluid tends to rise, the glucose and chloride readings remaining normal. Examination of the blood at this stage reveals a leucocytosis in most instances, the total white cell count rising as high as 25,000. There is a relative predominance of polymorphonuclear cells.

Even although such a meningeal reaction occurs, indicating as it does the invasion by the virus of the subarachnoid space, recovery may yet ensue without the development of paralytic phenomena, such cases constitute the so-called meningitic form of the disease.

The Appearance of Paralytic Phenomena

However, once the virus establishes itself within the nervous system, paralytic phenomena which vary with the localisation and intensity of the lesions make their appearance. The most acceptable classification of the clinical pictures resulting is one that comprehends cerebral, cerebellar, brainstem, spinal and a less certain neuritic form. Of these the spinal form is by far the commonest. In this paralyses of varying intensity and extent make their appearance with a suddenness which is all the more dramatic when the two preceding stages have been unnoticed or unrecognised. The generalisation that paralysis is always sudden in onset and maximal at this moment has its exceptions and in some cases the paralysis may ascend until it ends in respiratory paralysis, or may proceed from limb to limb in a series of jumps.

Of the paralyses themselves it is scarcely necessary to speak here, but certain aspects of the clinical picture may be mentioned. Of the total number of muscles initially affected the majority are but partially paralysed, and there occur cases in which a large number of muscles are but slightly impaired in voluntary power and none is profoundly paralysed. Such patients present an appearance of generalised slight weakness which may be mistaken for a post-febrile or a post-influenzal debility, so that the nature of the malady may be entirely overlooked from beginning to end. Such generalised weakness may be transient lasting for a period of days only, but when it occurs a systematic examination of the tendon jerks and of movements at all joints will generally reveal the existence of a local incidence of the disturbance, and thus betray its nature. In another group of cases, where both legs are profoundly or completely paralysed at onset, a period of two or three days' retention of urine is not uncommon. Again, in other cases with severe and extensive cord lesions, the white matter of the antero-lateral columns may be involved with the appearance of unilateral or bilateral Babinski plantar responses.

Pain is another frequent accompaniment of paralysis in the affected muscles. It may vary from slight pain on movement and manipulation of but a few days' duration to intense and widespread pain lasting for several weeks. It is possible that pain has a certain prognostic value in respect of the muscles in which it occurs. Careful examination will generally reveal that not all muscles are tender to pressure or painful on movement, and it has been my impression that in the early days of the illness, of a number of profoundly or totally paralysed muscles, those which are painful to pressure or manipulation are those which earliest show signs of recovery and regain power most rapidly, while those which are totally paralysed and painless are those which the subsequent course of the case will show to be permanently paralysed. During the first two or three weeks prognosis as to recovery of power is always difficult, and should experience prove this impression to be accurate, pain and tenderness may be a sign of definite prognostic value.

From what has been said of the preparalytic stages of poliomyelitis, it is clear that diagnosis at this period depends upon the recognition of the signs of subarachnoid invasion which I have enumerated. It must be confessed, however, that unless in the presence of an epidemic, or of well-developed general and meningeal reactions with the characteristic intermission between them diagnosis before the appearance of paralysis is likely to remain exceptional.

TREATMENT

When we come to consider questions of treatment it is clear that the pre- and post-paralytic stages of the malady present two distinct problems. During the former and the early days of the latter stages the infective character of poliomyelitis calls for appropriate measures, but an even more urgent problem arises during the preparalytic period, that of arrest of the infection before invasion of the central nervous tissue.

The Preparalytic Stage

Assuming that a diagnosis has been made with reasonable certainty at the onset of subarachnoid invasion there remains at most but a period of hours in which to arrest the progress of the infection. In respect of the use of drugs for this purpose there is only one substance, hexamine, of which trial has been made, and this, on the basis of some experiments of Flexner and Amoss. They found that on oral administration this substance can be detected in the cerebro-spinal fluid, and that the development of the experimentally produced disease in monkeys could be delayed, and in some instances prevented by keeping the animals under the influence of the drug both before and after inoculation. In the past, however, the use of hexamine in the customary dosage for infections of the nervous system has not given very promising results. Possibly the employment of massive doses with alkali, as has been suggested recently, might be more fruitful.

It has been found that the serum of convalescent or recent cases of poliomyelitis contains immune bodies, and the administration of such serum, both intrathecally, intravenously and subcutaneously, has been tried during recent epidemics. The method has given promising results in cases treated during the preparalytic stages in the form of a combined intrathecal and subcutaneous or intravenous administration. Since the serum of human convalescents is alone available for this purpose, it is obvious that, however encouraging we find these results, we have not yet available a method of serum treatment, either in itself reliable or equal to the demands which an epidemic of any severity would speedily make.

Whether or not lumbar puncture and thecal drainage during the meningeal stage has any therapeutic value is uncertain. It has been said that in patients with a brisk meningeal reaction the symptoms may be relieved by this means.

In respect of the infectivity of poliomyelitis, it is clear that the patient should be isolated and his secretions treated as infective since the nasopharynx is known to harbour the virus. Precautions to this end may in all probability, be safely given up three weeks after the temperature has fallen, as the presence of the virus after this period has not been recorded in the human subject.

Whether the routine use of antiseptic gargles has any other value than to impress upon the patient and his attendants the infective nature of his malady is problematical, but even this, though a modest, may be a useful function

The Postparalytic Stage.

The period of infectivity once passed, the treatment of the paralysed muscles alone remains It is not now possible to do more than formulate some general principles in respect of this During the remainder of the acute stage—that is, until the disappearance of pain and tenderness—no other therapeutic measures are permissible than rest and the prevention of deformities Local treatment, either as massage or electricity, are strongly contra-indicated, not merely as useless, but as calculated to aggravate the pain and to prolong its duration There is no need for me to stress the difficulties which this policy of apparent inactivity may present, in the face of the fantastic claims made for electrical procedures, and the faith which the public has in this and other mysterious forces Whatever we believe of the value of this form of treatment in the convalescent stage, it is most certainly unjustifiable during the acute stage Upon this point all experienced observers are now agreed

The prevention of deformities is achieved by placing the paralysed muscles as completely as possible in a position of physiological rest When, as so frequently happens, we are dealing with paralysis of adjacent and antagonistic groups of muscles this position must necessarily be one intermediate between full lengthening and shortening of the muscle, and as near the minimal length as possible

Various methods of *splinting* have been advocated to fix the limb in the desired attitude It is clear that the age and condition of the child and the degree of pain present will determine which method best suits the individual case We may, however, enter a warning against the total immobilisation of a limb for any length of time within a plaster splint, a method by which paralysed and intact muscles are alike completely fixed, to the great detriment of the latter

Re-education —With the arrival of the pain-free convalescent stage the maintenance of good posture, which remains essential, may be supplemented by more active procedures Placed in order of value, those adopted are active re-education exercises, massage, and electrical stimulation We may briefly dispose of the two last named There is an increasing consensus of opinion amongst experienced observers that at best electrical treatment in any form is of doubtful value and at worst is definitely harmful Harmful in that it is apt to replace valuable methods of treatment and to aggravate the imbalance between opposing muscles of variable degrees of weakness, and at best of doubtful value in that carefully observed cases which have been thoroughly dealt with by other means do as well without it as with it Lovett, of Boston, who carried out control observations on this point, failed to find evidence of benefit from electrical treatment

Massage undoubtedly has a most useful though restricted sphere of usefulness When carefully administered it maintains the inactive muscle in as good a condition as possible pending its renewed innervation It helps to preserve a useful effector organ for the restored neurone to innervate It has no other influence It is most valuable in the case of completely or profoundly paralysed muscles for which active exercise is out of the question

Unquestionably of primary importance, though far more difficult to obtain, is the re-education of the affected muscle by active exercise For every patient a scheme of such exercises must be drawn up according to the particular muscles concerned and corresponding to the degree of their weakness This must be revised from time to time as recovery proceeds Details of such exercises are to be found in Lovett's "Treatment of Infantile Paralysis" This active re-education involves the mobilising of the patient at the earliest possible moment Here we seem to run counter to a widely cited dictum that even momentary and slight stretching of a paralysed muscle permanently impairs its chances of recovery It seems to me that this sweeping statement is unsound on physiological grounds, and in practice condemns the patient to an indefinitely prolonged immobilisation which must react unfavourably upon the whole neuro-muscular system.

We now know from the researches of Sherrington and Liddell that stretching of the muscle-fibre is the normal physiological stimulus for the production and maintenance of muscle tone and other proprioceptive reflexes, and it seems incredible therefore that, within reasonable limits, a physiological stimulus can be essentially harmful.

INCIDENCE, SUSCEPTIBILITY, AND MODE OF SPREAD.

Like every other acute specific fever, poliomyelitis has its particular seasonal and age incidence, susceptibility factor, incubation period, and mode of spread

In its epidemic form it is a disease of late summer and autumn, August being usually the month of maximal case incidence But outbreaks occur at varying times from this into the winter It is characteristically a malady of early childhood, of the second to the fifth years of life After this period the case incidence falls rapidly, although it occurs throughout childhood and adolescence and, less commonly, in adult life The various estimates of the incubation period range from 2 to 12 days, from 3 to 4 days is probably the most common All available evidence indicates, to use the words of the Rockefeller monograph, that epidemic poliomyelitis is "a human-borne contagious affection, the portal of entry for the virus of which is the upper respiratory tract, in particular, the nasopharyngeal mucous membrane"

The infection is carried and spread by sufferers from the disease, both in its complete and its so-called "abortive forms," and also by healthy carriers In these the virus is present in the nasopharyngeal mucosa and in the secretion thereof It is probable that from this situation it gains access to the subarachnoid space through the perineural lymphatics of the olfactory nerve filaments, and having once gained such access may again pass out by the same channel into the nasopharynx.

In the case of the infected patient, the observations of Flexner and Amoss indicate that the virus generally disappears from the nasopharynx of convalescents within three weeks of the onset of the disease There is no evidence of the existence of chronic active carriers The longest known period of carriage by a healthy subject is that recorded by Amoss and Chesney, who detected the virus in the nasopharyngeal secretions of a healthy girl five days before she developed the disease Hence the presence of chronic carriers of either type is unproven The following case is of interest in relation to this question —

H J, a boy of 11, spent the month of August in Brittany, a known infected area He returned to his boarding-school in September and remained healthy until Nov 3rd, when with six other boys he went sick with sore-throat In all of them there was pyrexia of from 100° to 101° F and a typical condition of follicular tonsillitis On Nov 6th all the seven were released from the infirmary and went to morning chapel While dressing the boy in question noticed that his right leg was weak and ached somewhat On the way to chapel he was seen by the headmaster to fall down and to be unable to get up again That evening examination revealed definite weakness of moderate degree of several muscles in the right lower limb with loss of the knee-jerk The other six boys remained well

There are two possible interpretations of this episode That all seven boys suffered simultaneously from poliomyelitis, all but one proving abortive In this case no original source of infection is discoverable An alternative possibility is that H J alone suffered from poliomyelitis that he had been a healthy carrier since leaving Brittany, and that the faucial infection and resulting reaction allowed of active infection by a poliomyelitic virus already present On this view there is a known source of possible infection

The question of natural susceptibility and resistance is also of considerable practical importance, although, unfortunately, our knowledge of these factors is far from complete, in this as in other infective diseases Experience seems to indicate that there is a high resistance to infection by the poliomyelitic virus in the community at large Unlike measles, small-pox, and varicella, poliomyelitis will not vegetate on every soil Here, again, there are alternative speculations Conceivably, the great majority of infants suffer from an abortive form of the disease in early life and thus acquire that permanent immunity which known sufferers from the malady subsequently enjoy, and we know that when successive epidemics strike a community within a short period of years the victims tend to be those born since the previous epidemic On the other hand, those who fall victims to it may belong to a group of persons, of whose existence there is some evidence, in whom the healthy nasopharyngeal secretions lack the protective bodies which healthy individuals have been found to possess Interesting as such speculations may be, they do not provide any basis for practical action when the disease makes its appearance in a community in epidemic form

No account of the epidemiology of poliomyelitis can fail to take account of the recent investigations of W W C Topley and Major Greenwood on animal communities, and those of S F Dudley on certain semi-isolated human communities

Topley's observations indicate that within an isolated community of mice the spread of an infective disease can be limited by the segregation of the members into small groups, that it is increased by the addition to the herd of fresh susceptible individuals, and that even after the infection appears to have died down, the introduction of susceptibles will cause it to flare up anew

Dudley's observations have dealt with a series of infections, including sore-throat, influenza, mumps, German measles, scarlet fever, and diphtheria, maladies which are usually disseminated in droplets borne in the expired air of cases or carriers of disease Knowing that the virus of poliomyelitis inhabits the nasopharyngeal secretions and is spread by human contact, it is not unreasonable to consider it as a probable example of "droplet infection" Stated very incompletely and summarily, Dudley's observations indicate that dormitory infection is the principal mode of spread, which occurs in direct proportion to the proximity of the sleeping individuals In a mixed day- and boarding-school, diphtheria, contrary to what one might have expected, took its toll of the boarders and not of the day boys of that or of neighbouring schools Thus, Dudley says "In 1921 the morbidity for diphtheria at Greenwich Naval School was 1000 per 10,000, which is about 20 times greater than the estimate given above for London elementary school-children of the same age Most of the Greenwich boys are recruited from the Board Schools, and on entry showed about the same degree of herd immunity as is found in children of the same age at these schools Therefore, when the best specimens of County Council school-boys were transferred to another type of environment they suffered from a morbidity more than fourfold that which fell on similar boys who remained in the original environment" He adds that the figures for scarlet fever are almost identical with those for diphtheria The factor responsible for this increase seems clearly to be bed-to-bed infection in dormitories, and not class-room and play-ground infection There are many other aspects of Commander Dudley's investigations which make them of the greatest value, but these points will suffice for my present purpose

Outbreaks in Boarding-schools

Certain recent outbreaks of poliomyelitis in boarding-schools have brought home to us the necessity for practical measures based upon the available relevant facts of observation in respect of infective diseases The character of the desirable measures has given rise to considerable controversy, in which authoritative opinion has been found in support of each of two rival policies The matter is of sufficient importance to warrant some reflections

It seems to have been assumed by both parties to the controversy that one alone of the alternative policies advocated could be right the other being wholly and always unsound, that boarding-schools in which poliomyelitis appears must either of necessity be enclosed and quarantined, or, alternatively, must be broken up and the pupils dispersed Surely, to take this view in the present very incomplete state of knowledge is to place a very complex situation upon the procrustean bed of an unjustified generalisation There are obvious objections to either policy and it may be doubted whether either has a universal validity

In the first place it seems to me that the situation is dominated by the fact that the head of a school owes his first responsibility to the parents who have confided their children to his care. For him the safety of his little community takes precedence of that of the community at large This may be regrettable, but, unless and until the State intervenes with a contrary policy, is inevitable and must be faced

Starting from this assumption, is isolation of the school and quarantine or dispersal the sounder policy in the light of present knowledge? Surely, the answer to this question depends entirely upon local conditions

From what has been said, the minimal requirements of a safe isolation of the school community are the segregation of its members into small groups, each isolated from other groups, the sleeping of the individuals under such conditions that "droplet infection" cannot occur, and the strict exclusion of fresh susceptible members for a long period after the dying out of the infection

If these measures are not practicable, then the enclosure of the school community cannot be justified on its merits. In commentary we may say that in most boarding-schools they must prove wholly impracticable Further, we must bear in mind that poliomyelitis may lead to permanent and severe crippling in those who survive the infection, and that with the appearance of each fresh case the period of isolation and the chances of contact infection increase Finally, it may be asked, is it reasonable to expect a parent to allow his child to be shut up in the focus of infection of such a disease, as we know poliomyelitis to be, for an indefinite period? Each one may answer this question for himself

Against the policy of dispersal, on the other hand, there are also grave objections The dispersed individuals may be carriers and may spread the infection within the community at large Such is its usual mode of spread In assessing these dangers, as far as we can, we know that the disease is not highly infective, and that in its home the child can be so segregated on the lines indicated above as to reduce considerably the chances of spread Finally, as we have seen, the policy of dispersal may be unavoidable when safe enclosure is impracticable, or when irrespective of this, the parent decides the matter

It seems that the closest approach to a decision we can make is to say that under ideal conditions—and only under such conditions—enclosure of the infected school community is probably the method of choice In all other circumstances, dispersal may have to be resorted to In short, local conditions should decide the policy finally adopted in any given instance

---

PLYMOUTH HOSPITALS —Thanks to the penny-in-the-pound scheme, the income of the Plymouth Voluntary Hospitals Committee has much more than doubled during the last three years In 1926 the scheme produced £15,000 as against £6000 in 1924

PHYSIQUE OF POLICEMEN —The chief police surgeon for Bradford, Dr William Wrangham, and seven medical assistants have presented a report on policemen's physique to the City Watch Committee They state that the Bradford policeman "does not possess the stamina of the pre-war man, in other words, there has been a decline in the physical and psychic standards" Suggested steps for improvements are Sleeping with bedroom windows open, daily physical exercise, special care of the teeth, cold baths or a sponge-down on the advice of the police surgeon, inoculation of men susceptible to cold on the recommendation of the police surgeon, and two periods of duty of four hours each separated by four hours' rest, instead of eight hours' continuous duty The report was considered on Jan 28th by the Organisation Subcommittee of the Bradford Watch Committee, and it was decided to seek further information as to the reason for the alleged decline Statistics show that in Bradford there is a higher percentage of days lost through sickness than in any other town in the country except one The figures for 1925 are said to be Birmingham, 6, Manchester, Hull, and Cardiff, 7, Bristol, Liverpool, and Newcastle, 8 Salford, 9, Nottingham, 10; Bradford, 17, and Leeds, 19

SPA DOCTORS AND THE IMPROVEMENT OF NATIONAL HEALTH *

By RICHARD ACKERLEY, M B , B.Ch Oxf.,
LATE PHYSICIAN, LLANDRINDOD WELLS HOSPITAL

I propose to start by giving two texts The first is taken from the preface to a translation of one of Dr Carl v Noorden's works by Dr A. C Croftan, of Chicago —

> " In sanatoria and in watering places too much attention is generally bestowed upon the immediate result, too little upon the ultimate effect, the most important element of the treatment being always the education of the patient not for a few weeks but for the rest of his life "

The second text is the refrain of Rudyard Kipling's verses entitled " The Heathen," " All along o' dirtiness, All along o' mess, All along o' doin' things, Rather more or less "

Whatever his previous experience may have been, the purely spa physician has to do mainly with the chronic conditions of ill-health The duration of the actual symptoms of which the patient complains may vary from a few weeks to many years and may have been continuous or recurrent, but in any case they are rarely if ever seen at the spa in their early stages Too often the early symptoms have been treated too lightly, and this may be quite as much the fault of the patient as of the doctor.

Early symptoms are often slight and by both doctor and patient are treated with more or less indifference Symptoms are relieved without a proper investigation into their cause, but surely that is the time when it would be easier to effect a complete cure If a slight fire occurs in one's house, one does one's best to put in out as quickly and as effectually as possible In the body the *slightness* of a morbid condition and not the morbid condition itself seems to be dwelt upon, and vigorous and, if necessary, sustained methods are not made to eradicate it entirely For this, as I have said, the doctor is not wholly to blame Too often if he tries to press upon the patient the importance of getting at the cause of some slight affection, he is thought to be making a fuss, but the fact remains, if a patient has a pain he asks only, as a rule, the relief of the pain and not of the factors that have caused it and so on

Factors of Disease

As regards the factors of disease, with the exception of trauma and acute infections and some of the diseases which arise from occupation and environment, I think it will be generally agreed that chronic sepsis, especially sepsis of the upper part of the digestive and respiratory tracts, and faulty habits, are the causes of most of the morbid conditions of middle and advanced age In a sense one would say they are due entirely to faulty daily habits If this suggestion is correct that chronic sepsis and faulty habits are responsible for most of the morbid conditions which we are called upon to treat, it is necessary that the spa physician should make a careful study of daily habits—all habits, but especially of food habits—though clothing, exercise, ventilation, and so on are also most important He should be familiar with the régime of the nursery, as in the nursery habits are acquired that persist through life This is one reason why it is desirable that the spa doctor should not specialise until he has had some years of general practice As food and raiment are important, he should know more about them than he can have learnt at any medical school He must become acquainted with all the factors that can cause chronic disease—that is, if his aim at the spa is not merely to treat symptoms and get a temporary improvement but to secure as far as he can permanent cures It is the whole condition of the patient and not his symptoms that requires treatment A man is not suffering from high blood pressure or from fibrositis, but from the general deterioration of the body, the result of factors which have usually been in operation for a considerable time and which are most often still in operation I often say, when I hear that so-and-so has died from pneumonia, that he did not die from pneumonia but from the condition he was in when he got pneumonia It is not the last straw which breaks the camel's back, though we sometimes talk and act as though we believed in that misleading proverb.

Then again, in the disease which occupies so much space in the public view—cancer—the idea that is held by some surgeons that cancer can occur in the perfectly healthy body is, in my experience, absurd. Because a man has not complained of symptoms, it does not show he is healthy I have seen a large number of cases of malignant disease in general practice, and since I have been in spa practice have often been the first to discover it But never yet have I seen it except in a body in which there is already a more or less general fibrosis, and I think it is possible that we at the spas, better than any others, may be able to throw light on the precancerous condition

Chronic Sepsis

Now I will come to the gist of my address If we are agreed that the illnesses of middle life and old age are due to chronic sepsis and the gradual accumulation of toxins and waste matters in the body, with the gradual deterioration that comes from faulty habits, is it not of vital importance to us that we should be agreed as to the prevention and treatment of sepsis, and as to what should be the daily habits of the civilised man ?

I want to suggest that it may be a useful work in this section to arrive at agreement as to what we should teach, so that the layman should not be able to say, as he glibly does say, " But you doctors do not agree amongst yourselves and you tell us to do things, but do not practise them yourselves " These reproaches are too often merited Why cannot we do our best to wipe them out ?

Taking the two things that I have suggested as the main factors of middle-age disease—chronic sepsis and faulty daily habits—in order, the commonest form is dental sepsis, which is more or less generally recognised But the factors that caused it began in the nursery Dental sepsis itself in the form of marginal gingivitis is very common in children in early life and it is not adequately treated Over and over again when there has been a general septic condition affecting all the teeth I have known three or four of the worst teeth to have been removed and a vaccine, absolutely useless in my experience, to be made and injected, but the other septic teeth are permitted to remain In cases of sepsis it is surely not a question whether the sepsis is advanced or not, it is its presence This habit of half removing sources of dental sepsis is as foolish as it would be, if one's house were on fire in several rooms, to put the fire out in three rooms and leave it burning in two others where it was not burning so fiercely, and had not done so much damage

Another point about dental sepsis it is the fashion now, even when septic conditions are obvious to the eye, to have the teeth radiographed and, if there is not much obvious destruction of bone or apex of tooth, not to regard the condition seriously But septic conditions round teeth can exist for years before any change is shown in bone or teeth As in the case of a fire it is not the damage already done that is most important, but the damage that must result if the fire is not completely extinguished

It has been alleged that the treatment of dental sepsis has often resulted in *no* improvement to the patient I attribute the failure in many cases to the fact that the treatment has not been radical Some years ago Mr. St John Steadman read a paper at the Odontological Section of this Society on a case of rheumatoid arthritis twice cured by dental treatment My comment was that the teeth he took out on a second occasion were septic when he made his first extraction, hence the recurrence of the symptoms Secondly, it is, of course absurd to suppose that the extraction of teeth in itself is anything but harmful We have all come across cases when even the extraction of three or four teeth—the extraction of many teeth at a time should always be avoided—has caused an exacerbation of symptoms Further, a complete eradication of dental sepsis, though it provides for future safety, cannot possibly do anything to undo the damage already done

---

* Being the presidential address delivered to the Section of Balneology and Climatology of the Royal Society of Medicine

May I venture to quote two extracts from the Transactions of the Royal Society of Medicine[1] —

> "Another point to be remembered is that the longer the source of sepsis is permitted to remain the greater the damage to the tissues In young adults most marked and rapid improvement in a general condition will often follow dental treatment, while in those of advanced years the improvement is often slow and not so complete This difference is naturally to be explained by the fact that in the young the tissues have not been damaged beyond recovery, whereas in those of more advanced years the tissues are damaged beyond repair This, to my mind is a most important point and with increasing knowledge of these cases I think the tendency will be to insist more and more on the early removal of teeth in cases of dental sepsis, and so place the patient, so far as the mouth is concerned, in a safe position."

Again in the discussion on a paper by Dr (now Sir) Thomas Horder[2]—

> "Dr Ackerley expressed his general agreement with Dr Horder that oral sepsis, especially when chronic, had most serious results on general health, and was, he believed, a large factor in many of the diseases of middle life and old age, especially those in which fibrotic changes were a marked feature How far it was a factor could be known only to those who insisted not on its partial but on its entire removal He could not quite understand the attitude of those who allowed a septic condition to remain in the mouth because they doubted whether the results were as serious as had been suggested He thought their duty to their patients was to give them the benefit of the doubt and to remove a potential source even if they doubted its being the actual source of disease No one would suggest that a septic mouth was conducive of health"

Cannot we at some time, come to an agreement as to what our duties ought to be with regard to dental sepsis It will certainly be necessary if the spas take up the treatment of insured persons, to provide for the treatment of dental and other sepsis To me this presents considerable difficulty, as over and over again I have been assured by patients that their dentists have pronounced their mouths free of disease when sepsis has been neither slight nor obscure

FAULTY DAILY HABITS

I now come to the question of daily habits The first thing that occurs to one is, what should be our teaching as to habits of eating and drinking? It used to be a habit, and still may be a habit at some spas for doctors to have lists of all sorts of likely and unlikely foods provided, underlining various articles as desirable, others as permissible, and others as forbidden I have seen many of these lists and have often failed to understand on what process the selections were made In my own practice I find it is rarely necessary to prohibit any natural foods if plainly cooked Sugar and condiments &c I cannot regard as foods But I often find myself saying ' It is far less important what you eat than how you eat it " Food habits are important It would be a great boon to ourselves and to our patients if we could be agreed on our teaching regarding them Are the usual four or more meals a day good for the child and the apparently healthy? Or is the very frequency of meals for years, one of the causes of the dyspepsia of middle life, for in middle life the eupeptic individual is hard to find There may be no complaint of indigestion if one asks a patient, but there is constipation and flatulence, all serious signs of faulty digestion, in almost every patient one sees and examines carefully Is the usual afternoon tea with its cakes and sweets the harmful thing that our friend Dr. Leonard Williams suggests? I may say I am in full agreement with him Is the habit of eating and drinking together a habit common to civilised human beings, but I am told practically unknown among wild animals, right or wrong? Not only does the wild animal not eat and drink together, but if a man had a valuable horse likely to be a Derby winner, he would not allow it to be fed and watered at the same time, and if the mastication and insalivation of food are essential to digestion I venture to repeat a remark I made at the discussion on Alimentary Toxæmia, "that perfect insalivation does not occur when food and drink are taken together." I think the researches of Pavlov will confirm this Then, too can we not be agreed about some important articles of food? Is it of vital importance that a whole meal bread and not the emasculated substance usually called bread should be eaten by young and old? To help to prevent goitre, should children have iodised salt or have the iodine contained in the outer part of the grain of wheat? Is sugar—I mean refined sugar, not of course the natural sugar that is in fruits or honey—good or harmful? Is it harmful only when the middle-aged man or woman is ill, or is it harmful before he becomes ill and was it one of the factors causing his ill-health? Are beef and veal harmful to the Englishman and innocuous abroad? And is mutton so much more wholesome than beef? Hutchison suggests not But he does not point out that the Englishman eats mustard or horse-radish with his beef—nasty pungent substances which irritate the palate and stomach May I be permitted to interpolate here an observation that is not strictly à propos on the question of butcher's meat Fourteen years ago when I was in Egypt I began to notice the fat of meats There were there two sorts of beef, one local the meat of a small animal not overfed with very little fat and cold-storage meat laden with fat, the source of which was, I believe mostly Austrian I cannot vouch for this but whatever its source it was especially provided for the English consumer. As regards the flavour of the fat of the two kinds of meats the fat of the Egyptian animal was far more tender and far more palatable When I returned to England I began to notice the fat of English beef and mutton and found similar differences The fat of the Welsh sheep picking up its food naturally on the hills and not penned nor artificially fattened is lighter in colour and far less fibrous than the fat of mutton I see in London. The same applies to the difference between naturally fed and artificially fed beef. The most disgusting fat I ever saw or tasted was from a prize beast fattened for the Christmas show. I venture to suggest that the fat of artificially fattened animals and birds is like the fat of obese fibrotic men or women, and that it contains toxins that must be harmful if ingested.

Is milk a proper food for the child and the adult? How curious it is that except for man and the few animals to whom he gives it, no animal gets milk except at the suckling stage and only gets it then in such a way that it must be mixed intimately with saliva provided by mother nature so abundantly in the young that young animals have slobbery mouths Are the usual condiments so often forbidden when dyspeptic conditions are established or the kidneys affected only harmful then or were they factors in causing the dyspepsia, &c? Again, is the addition to almost all our food of one particular crystalline mineral salt sodium chloride, a substance the body hates and detests so greatly that it tries to eliminate it as rapidly as possible, essential or useful—or is it, as an increasing number of us believe a substance that from its insistence on being eliminated, interferes with the elimination of other waste matters from the tissues?

---

[1] Colver Discussion on Alimentary Toxæmia Proc Roy Soc Med March 1913

[2] Dental Sepsis from the Point of View of the Physician, Odontological Section Trans Roy Soc Med 1913-14

I do not wish to labour the question of habits but one or two others are of paramount importance.

Defective Oxygenation

It is more or less being recognised that in middle life and old age defective oxygenation is a large and important factor. It has occurred to me from clinical observation that toxins, of which we know so little, are like diamonds, very difficult to burn up. The toxin-filled body needs far more oxygenation than it gets or can get. It cannot get it first because from the fact that nearly all the activities of the upper part of the body are in the front of the body, and from defective daily exercises, the expansion of the chest diminishes as years increase, and secondly, ill-ventilated rooms with their moist stagnated air are a further bar to oxygenation.

Can we not be agreed and earnest in our teaching to secure full oxygenation of the body? We shall not do this as long as we shut our own windows and while professing to like fresh air, have a dislike to moving air and call it a draught. As Luciani, the Italian physiologist says, "It is an undeniable fact that the oxydising process is the most important in the animal body."

Water

Before I pass entirely from food, may I mention the question of water? I have suggested elsewhere that the ingestion of hot water and hot sloppy drinks are entirely harmful and shortly after I wrote my paper on that subject I found that the brothers Mayo in papers they wrote in 1915 and 1918 attributed the increase in cancer of the stomach largely to the ingestion of hot drinks; and also Mr Stuart Low has regarded cancer of the gullet as probably partly due to hot food. Yet I constantly find that doctors, including, I think, some here present advise the taking of hot water the first thing in the morning and at other times. No animal in creation except man ever swallows anything hotter than its body, and even the domestic dog has a dread of hot food. What is the right procedure? If hot drinks are wrong, think of the millions of wrongdoers in this country of ours! The fact that one million or one hundred millions of people do a foolish thing does not make it wise or good.

I mention these things—there are plenty of other things one could speak of if there were time—simply as part of my plea, that we should be agreed as to our teaching and not differ on matters of real importance. When in a paper I read in this Section on Fibrositis I endeavoured to show how gradually the body of a young child described by Dr Leonard Hill as "a glorious and perfect machine the heritage of millions of years of evolution," became a dirty body full of toxins and waste products with tissues hardened by the retention of those toxins, I was twitted by Dr Leonard Williams with having given a lecture on the laws of health. But it is precisely because spa doctors see more than anyone else the results of the violation of these laws that they should become more than others teachers and upholders of laws. *Gutta cavat lapidem non vi sed sæpe cadendo.* Why should one run, say, a valuable motor-car with every attention to detail and be careless how one runs a much more complicated and valuable machine, the human body?

As all present know there is a suggestion that the industrial classes should be treated at the spas. Is the treatment to be palliative or is it to be radical? If only palliative, if only the actual temporary disablement is to be attended to and no proper attempt is made to get at the factors that cause disablement, after a few years I feel sure, to put it in a modern phrase, the insurance societies will not find it a paying proposition. But if we take the line I suggested some years ago with reference to fibrositis for "complete cure and not for mere temporary relief, we must attend to all and not to one or two causal factors. It is the underlying condition and not some of its results that requires radical treatment," and acting on that we teach our patients not for a few months but for the rest of their lives. I think, that more and more the desirability of spa treatment for rich and poor would be recognised and we should have done not a little to improve national health. Of course the moment we begin to try to alter people's habits we shall begin to have trouble. May I tell you a little story? Many years ago a man about 55 went down to Llandrindod and met in the smoking-room of a hotel a friend of mine. He said he had come down to get treatment for gout and asked my friend if he knew any doctor he could recommend. He suggested myself. The patient, corpulent, plethoric, dyspeptic, prematurely old and very sorry for himself, came to see me. A day or two afterwards my friend met him again and learned he had been to see me. "And how did you like Ackerley"? "Not at all" was the reply. "He is the most impudent fellow I ever met. I came down here for baths and the waters for my gout and that fellow wanted to interfere with my habits." The story suggests the dangers we run if we try to alter habits, but surely the business of our profession should not be to get people out of ditches into which they have fallen but to prevent them falling into ditches? As we have to earn our living from our work an old rhyme occurs to me—

> Tickle the Public and make them grin,
> The more you tickle, the more you'll win
> Teach the Public, you'll never grow rich
> You'll live like a beggar and die in a ditch

But my own feeling is that when the public realise more and more the anxiety of a doctor to keep them in health the more they will consult him and the more they will trust him. Of course foolish people and those of our own profession who have acquired the habit of doing and advising "rather more or less" will call us faddists, but we need not be troubled by that. Semmelweiss and Lister in our own profession were denounced as faddists. It is true that the one was martyred—but the other was canonised. So Lord Wolseley was denounced as a faddist, but the people who denounced him would have produced an army in 1914 little better equipped and accoutred than Wellington's army in the Peninsula. To those who say they cannot be bothered about rules of living, they do not want to think about their bodies my reply is that if they do not think of the body the body will sooner or later make them think about it. It is a fact when habits are acquired we do not think of them, we perform them unconsciously.

In conclusion may I say, that our teaching must be with conviction, that is one of the main reasons why I plead for agreement between ourselves, what we shall preach and what we shall practise, and as in the physical body and in the body politic much harm ultimately results from half doing things and allowing the little evil to remain until it has become a great evil. Let us as Kipling says, "Keep away from dirtiness, keep away from mess, Don't get into doin' things rather more or less."

French Honour for Dublin Surgeon.—The Government of the French Republic has conferred the decoration of Officier de l'Instruction Publique on Mr William Doolin, F.R.C.S.I., in recognition of his services to French medical science and the development of fruitful relations between the Irish and French medical circles. Mr Doolin is editor of the *Irish Journal of Medical Science*, and recently represented the Royal Academy of Medicine in Ireland at the Laennec Centenary Celebrations in Paris.

PULSATION IN THE SUPERFICIAL VEINS OF THE EXTREMITIES

WITH DESCRIPTION OF A CASE

BY DAVID KRESTIN M D, M R C P LOND.
MEDICAL FIRST ASSISTANT, LONDON HOSPITAL

PULSATION in the superficial veins has always interested both clinician and physiologist, doubtless because it is easily observed. Such pulsation is not commonly seen in the veins of the extremities, and the following case is recorded both for its comparative rarity and the unusual features presented. No useful purpose would be served by attempting a complete review of the literature as full accounts have been given by Mackenzie[16] in 1894, in his exhaustive paper the Venous and Liver Pulses and Arrhythmic Contractions of the Cardiac Cavities; and more recently by Kerr and Warren.[14]

The earliest record of peripheral venous pulsation I have been able to find is that of Hombert,[12] cited from Friedreich[5] who in 1704, described pulsation in the veins of the neck and arms of a patient during periodic asthmatic attacks. In 1757 Albert Haller[10] referred to a patient who presented pulsation in all the superficial veins of both upper and lower limbs, the condition we are told, being found on post-mortem examination to be due to the presence of "polypi" within the beginning of the pulmonary artery obstructing the outflow of blood from the right ventricle. Isolated cases were described in the early part of the nineteenth century the earliest by Zulian[23] in 1805. Friedreich[6] in 1867, quotes Mayer who with Goubler and Verneuil noted pulsation limited to the varicose veins in one leg an observation presenting at least one feature in common with the following case:—

A Case of Peripheral Venous Pulsation

A married Jewess, aged 52, first came under the care of Dr Lewis Smith at the London Hospital in July 1919, when she was admitted for cardiac failure. She had been quite well until two years before when she began to complain of a cough and shortness of breath on exertion. Two weeks before admission her symptoms became much worse. Swelling of the feet, epigastric discomfort and palpitation kept her awake at night. She had no history of rheumatism, chorea or other illness. Of seven children all were alive and well, and she had had three miscarriages.

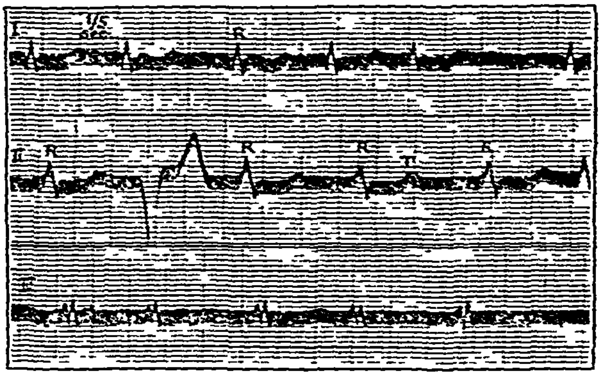
At this time the patient was a thin, tired-looking woman in obvious respiratory distress. She was slightly cyanosed and her feet were moderately œdematous. The pulse was small and completely irregular both in rhythm and force, the rate at the wrist was about 78 per minute. The apex-beat was in the seventh space, four and a half inches to the left of the mid-sternal line. Both cardiac sounds, completely irregular were audible in all areas. A presystolic murmur at the mitral area was described in the notes. The lungs were clear, except for a few inspiratory bubbling crepitations heard at the left base. The lower edge of the liver was felt one inch below the costal margin in the right mid-clavicular line, and there was slight tenderness on deep pressure over it. Hepatic pulsation was not recorded, nor was reference made to pulsation in any superficial veins. There were varicose veins on both legs. A diagnosis of mitral stenosis and auricular fibrillation was made, and after three weeks in bed on digitalis the patient was discharged much improved. She remained under observation as an out-patient, and except for occasional attacks of breathlessness, which were readily improved by digitalis, was able to carry on with her housework and the nursing of an invalid husband.

In August, 1924, on rising from bed, she found that her mouth was drawn to the right side, and her left arm and leg were paralysed. Consciousness was not lost, and after some hours she regained the use of her limbs. Two similar but slighter attacks followed within the next three months from which she made a complete recovery.

In June, 1925, one of the veins over her left tibia ruptured and she was readmitted to hospital. Her breathing was laboured and she was cyanosed, the ankles and shins were slightly œdematous. The apex-beat was diffuse heaving and disorderly, in the seventh space in the mid-axillary line. At the mitral area the first sound was followed by a long blowing systolic murmur conducted out to the left axilla and the second sound by a long diastolic murmur. These murmurs were less distinct in other præcordial areas. The lungs except for a few crepitations heard over the bases were clear. The superficial veins of both legs were exceedingly varicose tortuous, and prominent, the larger of these in the left leg measured fully half an inch across. It was then noticed that they were visibly pulsating and more careful examination of other superficial veins—viz., of the temples, neck, arms, dorsum of hands, chest, thighs, and feet—showed similar but less marked pulsation. The liver edge was now four inches below the costal margin in the right mid-clavicular line and there was distinct pulsation on palpation. The urine was free from albumin and sugar. The patient rapidly improved with rest, and was discharged after ten days.

From that time she has been able to carry out her usual household duties although with any attempt to exert herself beyond the ordinary, dyspnœa and palpitation caused enough distress to necessitate resting in bed for several days. Under such circumstances the patient was readmitted to hospital on three subsequent occasions. The predominating features always remained the same, and the venous pulsation was constantly noticed.

FIG 1.



Electrocardiogram showing auricular fibrillation, small amplitude of ventricular complexes (R) and an ectopic ventricular beat

She was last readmitted on July 23rd, 1926, in a condition much the same as before. There was a little orthopnœa, slight cyanosis of the lips, the respiratory rate being 20 per minute. The lungs were clear and have remained so throughout. The pulse was completely irregular in rhythm and in force: the rate on admission was about 60 per minute—she had been taking digitalis at home—and in hospital it remained about 70. The arteries were thickened and the blood pressure (brachial) was approximately 140 mm Hg systolic and 80 diastolic. There was extensive and heaving pulsation of the whole precordia, the apex-beat was in the seventh space in left mid-axillary line and the pulsation in its neighbourhood had a wavy appearance. The fifth to the eighth intercostal spaces inclusive in the left axilla showed well-marked retraction with each cardiac systole. The area of cardiac dullness reached upwards to the level of the upper border of the third costal cartilage, on the left to the apex-beat and on the right to half an inch external to the right border of the sternum. A long diastolic thrill was palpable over the apex. At the mitral area no first sound was heard but there was a long systolic murmur conducted outwards; the second sound was accentuated and followed by a long diastolic murmur. At the aortic area both sounds were present and distinct. The electrocardiogram (Fig 1) shows auricular fibrillation, small amplitude of the Q R S complexes, and ectopic ventricular beats.

A radiogram (Fig 2) was made by Dr M H Jupe, to whom I am indebted for the following report:—

"The film shows an enormous heart whose border extends fully to the left wall of the chest. The size is due to an enlargement of all chambers particularly of the left ventricle. There is no evidence of dilatation of the superior vena cava. The appearance is such that would be expected to result from extensive pericardial thickening and adhesions to surrounding structures. The very gross pulsation of the whole chest with each cardiac impulse, with the great size of the heart together made it unusually difficult to obtain a good film."

The superficial veins of the limbs showed pulsation as noticeable as on former examinations. In the left leg this could be distinctly seen at a distance of five feet from the hates and detests so greatly that it tries to eliminate it as rapidly as possible, essential or useful—or is it, as an increasing number of us believe, a substance that from its insistence on being eliminated, interferes with the elimination of other waste matters from the tissues ?

I do not wish to labour the question of habits but one or two others are of paramount importance

DEFECTIVE OXYGENATION

It is more or less being recognised that in middle life and old age defective oxygenation is a large and important factor It has occurred to me from clinical observation that toxins, of which we know so little, are like diamonds, very difficult to burn up The toxin-filled body needs far more oxygenation than it gets or can get It cannot get it first because from the fact that nearly all the activities of the upper part of the body are in the front of the body, and from defective daily exercises, the expansion of the chest diminishes as years increase, and secondly, ill-ventilated rooms with their moist stagnated air are a further bar to oxygenation

Can we not be agreed and earnest in our teaching to secure full oxygenation of the body ? We shall not do this as long as we shut our own windows and while professing to like fresh air, have a dislike to moving air and call it a draught As Luciani, the Italian physiologist says, "It is an undeniable fact that the oxydising process is the most important in the animal body"

WATER

Before I pass entirely from food, may I mention the question of water ? I have suggested elsewhere that the ingestion of hot water and hot sloppy drinks are entirely harmful, and shortly after I wrote my paper on that subject I found that the brothers Mayo in papers they wrote in 1915 and 1918 attributed the increase in cancer of the stomach largely to the ingestion of hot drinks, and also Mr Stuart Low has regarded cancer of the gullet as probably partly due to hot food Yet I constantly find that doctors, including, I think, some here present, advise the taking of hot water the first thing in the morning and at other times No animal in creation except man ever swallows anything hotter than its body, and even the domestic dog has a dread of hot food What is the right procedure ? If hot drinks are wrong, think of the millions of wrongdoers in this country of ours ! The fact that one million or one hundred millions of people do a foolish thing does not make it wise or good

I mention these things—there are plenty of other things one could speak of if there were time—simply as part of my plea, that we should be agreed as to our teaching and not differ on matters of real importance When in a paper I read in this Section on Fibrositis I endeavoured to show how gradually the body of a young child described by Dr Leonard Hill as "a glorious and perfect machine, the heritage of millions of years of evolution," became a dirty body full of toxins and waste products with tissues hardened by the retention of those toxins, I was twitted by Dr Leonard Williams with having given a lecture on the laws of health But it is precisely because spa doctors see more than anyone else the results of the violation of these laws that they should become more than others teachers and upholders of laws *Gutta cavat lapidem non vi sed sæpe cadendo* Why should one run, say, a valuable motor-car with every attention to detail and be careless how one runs a much more complicated and valuable machine, the human body

As all present know there is a suggestion that the industrial classes should be treated at the spas Is the treatment to be palliative or is it to be radical ? If only palliative, if only the actual temporary disablement is to be attended to and no proper attempt is made to get at the factors that cause disablement, after a few years I feel sure, to put it in a modern phrase, the insurance societies will not find it a paying proposition But if we take the line I suggested some years ago with reference to fibrositis for "complete cure and not for mere temporary relief, we must attend to all and not to one or two causal factors It is the underlying condition and not some of its results that requires radical treatment," and acting on that we teach our patients not for a few months but for the rest of their lives, I think, that more and more the desirability of spa treatment for rich and poor would be recognised and we should have done not a little to improve national health. Of course the moment we begin to try to alter people's habits we shall begin to have trouble May I tell you a little story ? Many years ago a man about 55 went down to Llandrindod and met in the smoking-room of a hotel a friend of mine He said he had come down to get treatment for gout and asked my friend if he knew any doctor he could recommend He suggested myself The patient, corpulent, plethoric, dyspeptic, prematurely old and very sorry for himself, came to see me A day or two afterwards my friend met him again and learned he had been to see me "And how did you like Ackerley" ? "Not at all" was the reply. "He is the most impudent fellow I ever met I came down here for baths and the waters for my gout and that fellow wanted to interfere with my habits" The story suggests the dangers we run if we try to alter habits, but surely the business of our profession should not be to get people out of ditches into which they have fallen, but to prevent them falling into ditches ? As we have to earn our living from our work an old rhyme occurs to me—

Tickle the Public and make them grin,
The more you tickle, the more you'll win
Teach the Public, you'll never grow rich
You'll live like a beggar and die in a ditch

But my own feeling is that when the public realise more and more the anxiety of a doctor to keep them in health the more they will consult him and the more they will trust him Of course foolish people and those of our own profession who have acquired the habit of doing and advising "rather more or less" will call us faddists, but we need not be troubled by that Semmelweiss and Lister in our own profession were denounced as faddists It is true that the one was martyred—but the other was canonised So Lord Wolseley was denounced as a faddist, but the people who denounced him would have produced an army in 1914 little better equipped and accoutred than Wellington's army in the Peninsula To those who say they cannot be bothered about rules of living, they do not want to think about their bodies my reply is that if they do not think of the body the body will sooner or later make them think about it It is a fact when habits are acquired we do not think of them, we perform them unconsciously

In conclusion may I say, that our teaching must be with conviction, that is one of the main reasons why I plead for agreement between ourselves, what we shall preach and what we shall practise, and as in the physical body and in the body politic much harm ultimately results from half doing things and allowing the little evil to remain until it has become a great evil Let us as Kipling says, "Keep away from dirtiness keep away from mess, Don't get into doin' things rather more or less"

FRENCH HONOUR FOR DUBLIN SURGEON—The Government of the French Republic has conferred the decoration of Officier de l'Instruction Publique on Mr William Doolin, F R C S I, in recognition of his services to French medical science and the development of fruitful relations between the Irish and French medical circles Mr Doolin is editor of the *Irish Journal of Medical Science* and recently represented the Royal Academy of Medicine in Ireland at the Laennec Centenary Celebrations in Paris return, and Claud Bernard[1] obtained pulsation in the veins of the submaxillary salivary gland as the result of dilatation of the arterioles following stimulation of the chorda tympani nerve

Centrifugal Pulse—This is the form occurring in the case above reported For the most part it has been ascribed to tricuspid regurgitation—the immediate retrograde propulsion of blood from the right ventricle to the right auricle and thence to the great veins—and no doubt this is the simplest mechanical explanation. It is now well recognised, however, that such pulsation may occur quite independently of any tricuspid lesion Vaquez[26] emphatically declares that the examination of the venous pulse gives no indication whatever of the condition of the tricuspid valve Graves,[7] cited by Mackenzie,[16] attributes this form of pulsation to the independent contractility of the walls of the veins themselves The ability of the great veins to contract was first described by Haller[8] in 1757 Brunton and Fayrer[3] demonstrated such contractions in the pulmonary veins of a cat, and McWilliam[18] described a rhythmic contractile state of the ostia of the great veins in fish

Two Varieties of Centrifugal Venous Pulse

Analysis by means of polygraphic tracings has resulted in the recognition of two forms of centrifugal venous pulse

1 *Negative or Auricular Form*—The part played by the right auricle in the production of venous pulsation has long been known Haller[8] and other physiologists asserted in the middle of the eighteenth century that the auricles could discharge blood backwards into the veins, and Morgagni[20] recognised clinically a venous pulse resulting from this Indeed, Potain[22] described such a pulse in the neck veins of normal individuals, which from inspection alone he recognised as being presystolic in time Further, Eichorst[4] noted a similar pulse in the veins of the forearm of a patient who had heart failure but no clinical evidence of tricuspid incompetence The jugular tracings in cases with a negative venous pulse show an "a" wave which may or may not be exaggerated

2 *Positive or Ventricular Form*—This is characterised in the tracings by a large premature "v" wave, and absence of the "a" wave For a long time this type of pulsation in the veins was considered practically pathognomonic of tricuspid incompetence This view seems to be supported by Kerr and Warren[14] and Middleton,[19] who have described pulsation in the superficial veins of the upper extremities of patients suffering from advanced cardiac decompensation and manifesting features of tricuspid incompetence—e g, evident cyanosis, gross œdema, pulmonary congestion, and albuminuria But evidence accumulates showing that tricuspid incompetence is by no means an invariable factor in the production of this type of pulse Friedreich,[5] basing his views on a considerable number of cases, came to the conclusion that its occurrence was independent of any valvular lesion Rihl[25] arrived at the same conclusion by experiment On the other hand, the importance of the right auricle in this connexion has received greater recognition since the pioneer work of Mackenzie[16] and Hewlett[11] The part it plays in the production of the negative form of pulse has been referred to already

Mackenzie[17] describes three conditions in which the ventricular or positive venous pulse may occur the onset of auricular fibrillation (by far the most common), great distension of the right auricle, and certain forms of regular tachycardia where the contractions originate at some abnormal site in the genetic system Whatever the condition, the one constant factor is engorgement of the right auricle with stasis of the blood stream passing through it In certain forms of tachycardia and occasionally in heart-block, the simultaneous 'contraction of the auricle and ventricle results in an overlapping of the 'a' and "v" waves, so producing one large wave in the phlebogram This as has been shown by Hewlett Mackenzie, and others, may produce abnormal visible pulsation in the neck veins But with a dilated and engorged right auricle a similar pulsation may occur apart from such a mechanism As Mackenzie[16] first pointed out, the "v" wave in normal jugular tracings is due to the overfilling of the right auricle from the veins at the end of ventricular systole Where the auricle is in a constant state of engorgement and stasis, this wave will be more prominent and occur earlier in the cardiac cycle But I do not think that this in itself would be enough to account for any well-marked pulsation, and a more important factor must be considered In normal circumstances the auricles are more or less empty at the beginning of ventricular systole, but in conditions where the auricle is constantly distended it will act like an inflated balloon, and readily transmit to veins communicating with it any impulses received from adjacent structures Thus the explanation offered by Vaquez[26] seems both simple and probable According to him, this form of venous pulse is produced by the retrograde shock received by the dilated right auricle from the contracting right ventricle, this shock being transmitted through the auriculo-ventricular wall, and may thus occur in the absence of any tricuspid lesion

Friedreich's Sign—One other cause of pulsation remains to be considered In the forms already mentioned the pulsation was due to a distension of the walls of the vein during cardiac systole Friedreich[6] described, in patients having pericardial adhesions, a pulsation in the neck due to an emptying of the veins during diastole with consequent collapse of their walls This has been confirmed by later observers Such a diastolic collapse would, by increasing the difference in venous pressures during systole and diastole, exaggerate any existing tendency to pulsation from causes already mentioned The explanation of this phenomenon first offered by Friedreich seems most probable Owing to adhesions of the pericardium to the anterior chest wall, the latter is forcibly drawn inwards with each cardiac systole At the moment this ends, the elasticity of the chest wall causes it to recoil briskly, resulting in a lowering and flattening of the dome of the diaphragm This pulls the heart down and increases the negative pressure within the thorax so determining a collapse of the veins during diastole The effect of this mechanism would be further supplemented by adhesions of the walls of the right auricle to surrounding structures tending to keep this chamber dilated

Mechanism of Pulsation in the Case Described

We may now consider to what factors may be attributed the striking pulsation described in our patient Its wide distribution and the fact that it is best seen over the anterior surface of the tibia excludes the possibility of transmission by contact with the large arteries Contraction of the veins themselves does not, so far as is known, produce venous pulsation in man As previously pointed out, the pulsation in our patient is centrifugal, and the polygram shows it to be of the "positive" or "ventricular" form Although manifestations of a gross tricuspid incompetence are absent, we have just those conditions which would favour stasis and great distension of the right auricle—namely, old-standing mitral stenosis with auricular fibrillation and resulting venous stasis The presence of adhesions anchoring the external walls of the auricle to surrounding structures must also be considered as a likely factor in maintaining dilatation of this chamber Although the venous pressure was not measured accurately, the height above the chest wall at which the veins of the forearm are seen to collapse, is always a useful indication of the degree of stasis in the right auricle The normal level, though somewhat variable, is generally about 5 or 6 inches As already pointed out, this height in our case was 12½ inches It is just under such conditions that the retrograde shock from the contracting right ventricle would bed The venous pulse was approximately synchronous with the arterial pulse On raising either arm or leg to a height of 12½ inches above the chest wall, with the patient in the recumbent position, the veins became empty and pulsation disappeared, maximal pulsation was observed at a height of 11 inches above the level of the chest wall After a segment of vein had been emptied by stroking with one finger it rapidly filled from the distal end, when filling from the proximal or cardiac end was prevented by digital pressure Pulsation, however, did not return until the proximal obstruction was removed, thus showing that the pulsation was centrifugal—i e, propagated from the heart to the periphery A systolic shock could be heard over the larger veins on auscultation with the stethoscope Fig 3 shows a tracing from one of the tributaries of the left internal saphenous vein The venous wave is seen to occur slightly later than the radial pulse Examination of the fundus oculi at no time revealed pulsation in the retinal veins The liver was enlarged as before and pulsated synchronously with the apex-beat Bimanual examination showed the pulsation to be expansile, and on one occasion examination in the "knee-elbow" position did not alter its degree There was no œdema of the extremities The amount of urine averaged 40 ounces in the 24 hours and contained no albumin. The Wassermann reaction was negative

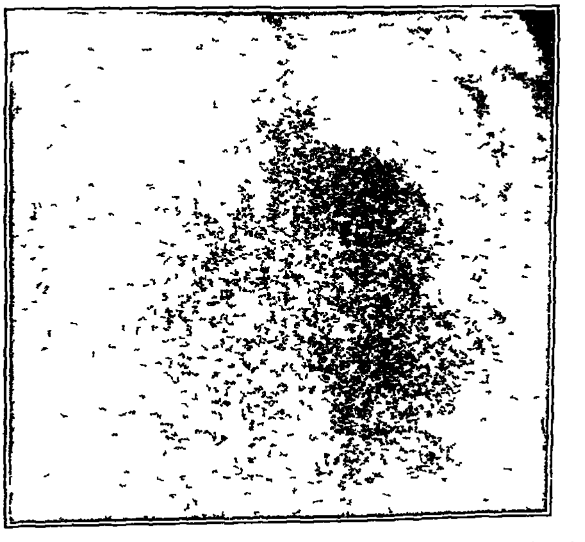
The patient was discharged on Sept 17th and remains under observation Her general condition is still fair and the physical signs unaltered

Diagnosis

In discussing this case we must consider (*a*) the interpretation of the cardiac physical signs above described, (*b*) the cause of the pulsation of the veins, and (*c*) what light, if any, is thrown upon the significance of abnormal venous pulsation in general

Cardiac Lesions—There can be little doubt the case is primarily one of mitral stenosis and auricular fibrillation The electrocardiogram and the polygraph tracing which shows the absence of "a" waves confirm the diagnosis of fibrillation The degree of cardiac enlargement, the large area of systolic retraction of the chest wall, the wavy character of the cardiac pulsation, and the radiographic appearance of the heart, all point to the presence of old obliterative pericarditis with extensive adhesions to surrounding structures Such a condition could be simulated only by pericardial effusion or aortic incompetence The former is excluded by the duration of the signs, the general condition of the patient, and the radiogram, in support of the latter there is no direct evidence on examination

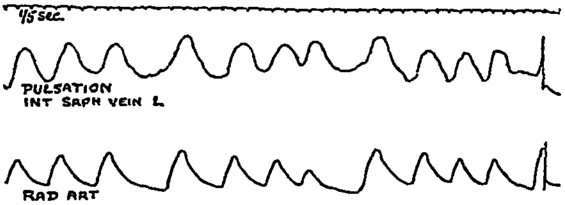
Fig 2



Radiogram showing extreme enlargement of heart both right and left The cardiac outline is seen within the shadow of the large mammæ

Apart from the abnormal condition of the veins and the liver, there is little evidence of a *gross* tricuspid regurgitation. A separate and distinct tricuspid murmur was never heard The size of the right heart is by no means out of proportion to the general increase in the size of the whole heart. The other clinical features of gross tricuspid incompetence are conspicuously absent Considering the great degree of general cardiac disability, there was always remarkably little cyanosis, and except under conditions of stress, little dyspnœa The lungs were almost free from congestion, and œdema of the legs was not present during her last stay in hospital The veins of the face and neck were not distended during periods of rest, and Bamberger's jugular bulb was never present The urine was never abnormal It will be observed, however, that I have qualified the term tricuspid regurgitation by the adjective "gross," for there is reason to believe that minor degrees of regurgitation at this valve are by no means uncommon. At autopsy, lesser endocarditic changes are commonly found in the tricuspid valve of hearts showing the more obvious pathological lesions of the mitral valve and pericardium Thus, at the Pathological Institute of the London Hospital, it was found that in 51 consecutive examinations at which mitral endocarditis was found, 22 (42 per cent) showed organic changes in the tricuspid valves The frequency with which this valve is affected in acquired heart disease seems from the general descriptions in text-books to be insufficiently recognised Moreover, quite apart from the lesser degrees of regurgitation occurring as the result of organic changes in this valve, it is well recognised that incompetence may readily occur in a normal heart under conditions of the slightest strain on the right ventricle—long, indeed, before such strain is great enough to produce abnormal objective signs in the patient John Hunter[13] and Richerand[24] both considered the tricuspid valve to be naturally incompetent, and Wilkinson King[15] in his classical experiment on the dead heart showed that this valve would not prevent the regurgitation of water even under moderate tension

Fig 3



Polygram showing, above, the pulsation obtained from a receiver applied to a tributary of the left saphenous vein above the ankle and, below, the irregular radial pulse

Conditions giving Rise to Abnormal Venous Pulse

There are two main types of venous pulsation in the peripheral veins—viz, the centripetal and the centrifugal

Centripetal Pulse—In this type the pulse wave is propagated from the periphery towards the heart, and nearly all the recorded cases of peripheral venous pulsation are of this nature Moreover, it is now well established that it may occur in both normal and abnormal states Thus Wilkinson King[15] observed it in himself after taking a heavy meal, and discussed its occurrence in the limbs as the result of warmth and exercise Similar observations were made by White[28] and others Such pulsation has also been described in a variety of pathological conditions—e g, neurasthenia, chlorosis, fever, and (most often) in aortic incompetence Both Quincke[23] and Broadbent[2] described it in such cases, and recognised on clinical grounds that it was due to the transmission of the pulse wave in the arterioles, through the capillaries to the veins This has also been demonstrated experimentally Palmer[21] produced it in a frog's leg by obstructing the venous return, and Claud Bernard[1] obtained pulsation in the veins of the submaxillary salivary gland as the result of dilatation of the arterioles following stimulation of the chorda tympani nerve

Centrifugal Pulse —This is the form occurring in the case above reported For the most part it has been ascribed to tricuspid regurgitation—the immediate retrograde propulsion of blood from the right ventricle to the right auricle and thence to the great veins—and no doubt this is the simplest mechanical explanation It is now well recognised, however, that such pulsation may occur quite independently of any tricuspid lesion Vaquez[26] emphatically declares that the examination of the venous pulse gives no indication whatever of the condition of the tricuspid valve Graves,[7] cited by Mackenzie,[16] attributes this form of pulsation to the independent contractility of the walls of the veins themselves The ability of the great veins to contract was first described by Haller[8] in 1757 Brunton and Fayrer[3] demonstrated such contractions in the pulmonary veins of a cat, and McWilliam[18] described a rhythmic contractile state of the ostia of the great veins in fish

Two Varieties of Centrifugal Venous Pulse

Analysis by means of polygraphic tracings has resulted in the recognition of two forms of centrifugal venous pulse

1 *Negative or Auricular Form* —The part played by the right auricle in the production of venous pulsation has long been known Haller[8] and other physiologists asserted in the middle of the eighteenth century that the auricles could discharge blood backwards into the veins, and Morgagni[20] recognised clinically a venous pulse resulting from this Indeed, Potain[22] described such a pulse in the neck veins of normal individuals, which from inspection alone he recognised as being presystolic in time Further, Eichorst[4] noted a similar pulse in the veins of the forearm of a patient who had heart failure but no clinical evidence of tricuspid incompetence The jugular tracings in cases with a negative venous pulse show an " a " wave which may or may not be exaggerated

2 *Positive or Ventricular Form* —This is characterised in the tracings by a large premature " v " wave, and absence of the " a " wave For a long time this type of pulsation in the veins was considered practically pathognomonic of tricuspid incompetence This view seems to be supported by Kerr and Warren[14] and Middleton,[19] who have described pulsation in the superficial veins of the upper extremities of patients suffering from advanced cardiac decompensation and manifesting features of tricuspid incompetence—e g , evident cyanosis, gross œdema, pulmonary congestion, and albuminuria But evidence accumulates showing that tricuspid incompetence is by no means an invariable factor in the production of this type of pulse Friedreich,[5] basing his views on a considerable number of cases, came to the conclusion that its occurrence was independent of any valvular lesion Rihl[25] arrived at the same conclusion by experiment On the other hand, the importance of the right auricle in this connexion has received greater recognition since the pioneer work of Mackenzie[16] and Hewlett[11] The part it plays in the production of the negative form of pulse has been referred to already

Mackenzie[17] describes three conditions in which the ventricular or positive venous pulse may occur the onset of auricular fibrillation (by far the most common), great distension of the right auricle, and certain forms of regular tachycardia where the contractions originate at some abnormal site in the genetic system Whatever the condition, the one constant factor is engorgement of the right auricle with stasis of the blood stream passing through it In certain forms of tachycardia and occasionally in heart-block, the simultaneous contraction of the auricle and ventricle results in an overlapping of the " a " and " v " waves, so producing one large wave in the phlebogram This, as has been shown by Hewlett Mackenzie, and others, may produce abnormal visible pulsation in the neck veins But with a dilated and engorged right auricle a similar pulsation may occur apart from such a mechanism As Mackenzie[16] first pointed out, the " v " wave in normal jugular tracings is due to the overfilling of the right auricle from the veins at the end of ventricular systole Where the auricle is in a constant state of engorgement and stasis, this wave will be more prominent and occur earlier in the cardiac cycle But I do not think that this in itself would be enough to account for any well-marked pulsation, and a more important factor must be considered In normal circumstances the auricles are more or less empty at the beginning of ventricular systole, but in conditions where the auricle is constantly distended it will act like an inflated balloon, and readily transmit to veins communicating with it any impulses received from adjacent structures Thus the explanation offered by Vaquez[26] seems both simple and probable According to him, this form of venous pulse is produced by the retrograde shock received by the dilated right auricle from the contracting right ventricle, this shock being transmitted through the auriculo-ventricular wall, and may thus occur in the absence of any tricuspid lesion

Friedreich's Sign —One other cause of pulsation remains to be considered In the forms already mentioned the pulsation was due to a distension of the walls of the vein during cardiac systole Friedreich[6] described, in patients having pericardial adhesions, a pulsation in the neck due to an emptying of the veins during diastole with consequent collapse of their walls This has been confirmed by later observers Such a diastolic collapse would, by increasing the difference in venous pressures during systole and diastole, exaggerate any existing tendency to pulsation from causes already mentioned The explanation of this phenomenon first offered by Friedreich seems most probable Owing to adhesions of the pericardium to the anterior chest wall, the latter is forcibly drawn inwards with each cardiac systole At the moment this ends, the elasticity of the chest wall causes it to recoil briskly, resulting in a lowering and flattening of the dome of the diaphragm This pulls the heart down and increases the negative pressure within the thorax so determining a collapse of the veins during diastole The effect of this mechanism would be further supplemented by adhesions of the walls of the right auricle to surrounding structures tending to keep this chamber dilated

Mechanism of Pulsation in the Case Described

We may now consider to what factors may be attributed the striking pulsation described in our patient Its wide distribution and the fact that it is best seen over the anterior surface of the tibia excludes the possibility of transmission by contact with the large arteries Contraction of the veins themselves does not, so far as is known produce venous pulsation in man As previously pointed out, the pulsation in our patient is centrifugal, and the polygram shows it to be of the " positive " or " ventricular " form Although manifestations of a gross tricuspid incompetence are absent, we have just those conditions which would favour stasis and great distension of the right auricle—namely, old-standing mitral stenosis with auricular fibrillation and resulting venous stasis The presence of adhesions anchoring the external walls of the auricle to surrounding structures must also be considered as a likely factor in maintaining dilatation of this chamber. Although the venous pressure was not measured accurately, the height above the chest wall at which the veins of the forearm are seen to collapse, is always a useful indication of the degree of stasis in the right auricle The normal level, though somewhat variable, is generally about 5 or 6 inches As already pointed out, this height in our case was 12½ inches It is just under such conditions that the retrograde shock from the contracting right ventricle would have its maximum effect on the right auricle and on the veins opening into it. This would be further enhanced by the hypertrophied walls of the right ventricle, such as we know occurs in long-standing stenosis of the mitral valve

The "v" wave in this case occurs very early in the cardiac cycle and this is a common feature of auricular engorgement Normally it results from an "overfilling" of the right auricle towards the end of ventricular systole, but when the auricle is constantly full, as must be the case here, the effect of overfilling will manifest itself by distending the cervical veins at the beginning of ventricular systole At this time, too the retrograde wave from the contracting right ventricle will be transmitted to the jugular veins, and tend to overlap and reinforce the "v" wave due to auricular "overfilling."

Although auricular stasis would explain the mechanism by which the pulsation is propagated to the veins, it seems hardly enough to account for the extent and degree to which it is observed in this case Two contributing factors must be considered —

(*a*) *Adherent Pericardium* —Evidence proving the presence of an adherent pericardium has been given, and the effect of this on any tendency to venous pulsation has been discussed

It was observed that when this patient was at rest the cervical veins were at no time markedly distended, whereas during diastole distinct flattening occurred Little attention has hitherto been given to the part played by pericardial adhesions in abnormal venous pulsation Many, indeed have denied it This is certainly not a constant factor, but it is at least significant that in a series of ten consecutive cases in which definite abnormal venous pulsation in the neck was recorded, and in which the heart was examined at autopsy, pericardial adhesions were present in six of them, and in two of these cases there was no evidence of a tricuspid lesion either during life or at necropsy.

(*b*) *Varicose Veins* —Attention has also been drawn to the great varicosity of the veins of the legs Varicose veins have long been attributed to a congenital weakness in the structure of their walls, a deficiency in the function of their valves, or both There is, therefore, some justification for considering that there may be a general incompetence of all the veins in this case The importance of local changes in the veins themselves as a factor in venous pulsation was fully discussed by Friedreich[5] who refers to a case described by an earlier writer, in addition to several he himself observed It seems not unreasonable to suppose, then, that the marked heave of the venous impulse, as seen in the legs, for example, may be partly explained by the state of the veins themselves

The question of the liver pulsation is beyond the scope of this paper It is now well established that it is always similar in character to the centrifugal venous pulse in the neck, and depends upon the same mechanism for its production Acting like a sponge it rapidly becomes distended with blood as soon as sufficient stasis and congestion in the right side of the heart occurs Wenckebach [27] has shown that this is always more marked in those cases where the pericardium is adherent Any change in venous pressure within the right auricle will be readily transmitted to the liver by the large hepatic veins with which this chamber is in direct communication

An interesting point already noted was the absence of pulsation in the retinal veins in this patient As a rule, where the pulsation in the peripheral veins is well marked, a similar pulsation is seen in the retina As was suggested by Dr Lewis Smith the large cavernous sinus with its rigid walls may well absorb much of the force required for propagating the venous stream backwards, and so the pulsation reaching the very small retinal veins may be reduced to a minimum

Prognosis

No description of such a case as this would be complete without some reference to prognosis Hitherto venous pulsation occurring in the extremities has always been regarded as evidence of advanced heart failure and of grave prognostic significance. The following statement by Kerr and Warren[14] seems to represent the general opinion "Pulsations elsewhere than in the neck and basilic veins, veins of the hand, and the retinal vessels, seem to be uncommon in our experience, except in cases of marked decompensation with pronounced regurgitation and engorgement In all such cases the prognosis was very bad and the patient died soon after. In this they resembled the cases in the literature." In the case above described pulsation has been observed for over 18 months, and it is quite possible that it existed before then As her condition is at present not much worse than it was when pulsation was first noted it must be concluded that venous pulsation in the extremities is not necessarily incompatible with a continuance of life for a period of many months

Summary

A case is described of auricular fibrillation, mitral stenosis, and adherent pericardium, exhibiting remarkable pulsation in *all* the superficial peripheral veins The absence of clinical features suggesting gross tricuspid incompetence is noted The more important causes of general venous pulsation are discussed, and evidence is adduced to show that tricuspid regurgitation is neither a constant nor an important factor.

A combination of (1) stasis and engorgement of the right auricle, (2) adherent pericardium, and (3) relative weakness, congenital or acquired, of the walls of the veins is considered the most likely explanation in this case Finally, it is pointed out that such pulsation need not necessarily affect the immediate prognosis

My thanks are especially due to Dr Lewis Smith for permission to publish this case, and for his valued help and advice Prof H M Turnbull allowed me to consult the records of his department in this connexion To Dr John Parkinson I am greatly indebted for the cardiogram, and for suggestions and help

Clinical and Laboratory Notes.

A CASE OF SPIROCHÆTOSIS ICTEROHÆMORRHAGICA

By A. Cowan Guthrie M B . C M Edin

Spirochætosis icterohæmorrhagica is a rare disease in England, although several cases have been described recently from Norfolk [1] Owing to its rarity I venture to give a somewhat detailed account of the history, various phases and progress of this affection as it occurred in a patient whom I attended.

History —On April 23rd, 1925 I was first called to see the invalid, a single lady in early middle age. She informed me that she had just returned from a visit to Egypt and that towards the end of her stay there she had begun to suffer from general malaise. Her health did not improve during the homeward journey and in addition a tendency to sickness began to supervene. On her arrival in England she still felt rather weak and out of sorts although not seriously ill

Examination.—The patient was lying in bed looking apathetic and somnolent, the pulse 76 temperature 98 6° F, the tongue coated with a yellowish-white fur On abdominal examination no splenic enlargement could be detected or tenderness in the region of the gall-bladder, hepatic dullness was only slightly increased In the somewhat poor light of the room the skin generally showed a yellowish tinge which took on a deeper hue in the conjunctiva. The usual remedies for such a condition were prescribed—a mild saline in the morning a mixture of bismuth and bicarbonate of soda before food, a euonymin pill at night, and a milk diet.

As, however, the patient's condition did not improve I was called to see her again on April 27th. The jaundice was now apparent and she complained of sickness On re-examination no tenderness over the gall-bladder or over any part of the abdomen could be detected.

The urine on examination showed a few leucocytes and numerous epithelial cells of vesical and renal origin (pelvis and calyces), all bile-stained. No tube casts were present. Chemical examination showed a trace of albumin no blood, a positive reaction for bile 1 per cent., and also the presence of indican. Examination of the blood showed hæmoglobin deficiency. There was variability of the red cells in size and shape, many cells appearing frayed, and there was variability also in their staining qualities although there was no basophilic degeneration. No spirochætes were found, or evidence of protozoal infection in either the red or white cells The differential count of the white cells presented fairly normal features, the leucocytes showing variable staining qualities as well as evidence of degenerative changes by the presence of fatty granules The Widal test was negative.

Up to this time the case was considered one of simple catarrhal jaundice which had resisted the usual methods of treatment. In order to determine whether or not there was obstruction van den Bergh's test was utilised, the result being indirect reaction positive with negative direct reaction, indicating toxic jaundice including catarrhal.

On April 28th the patient seemed somewhat better and the slight improvement was maintained throughout the next day till late in the evening, when there was a recurrence of the sickness the vomit being dark in colour This condition slightly improved during the next 24 hours

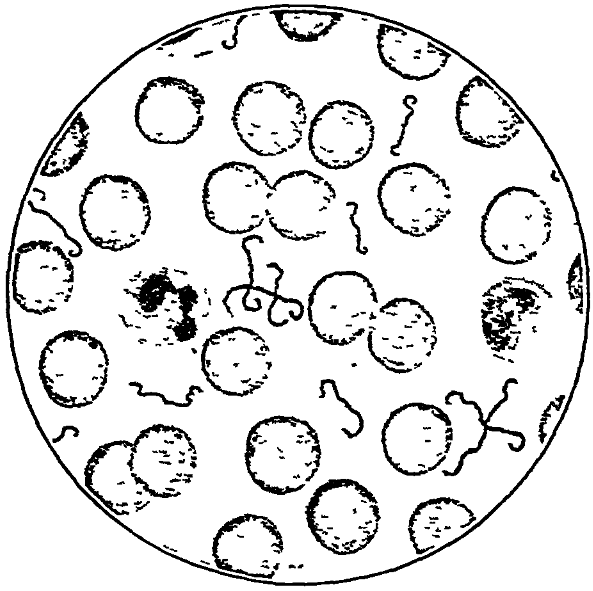
When I called on the morning of May 1st the patient looked very ill, the pulse was feeble, the temperature subnormal, and there was occasional retching and vomiting of dark coffee-ground material The next day the patient's condition appeared critical and she tended to lapse into a semi-comatose condition. Colon irrigations of a mixture containing sodium bicarbonate and citrate were administered and this mixture also was given orally with no beneficial effect It became apparent that the patient was suffering from profound toxæmic jaundice and symptoms of bronchial catarrh now appeared

On examination of the blood collected on May 1st spirochætes were discovered for the first time, and in enormous numbers • they were present also though to a lesser extent, in the urine collected on the same date Immune horse serum was given intramuscularly with no beneficial result. Lumbar puncture was performed to obtain cerebro-spinal fluid and on examination this showed no excess of either albumin, globulin, or chlorides. It contained 4 1 lymphocytes per c.mm. and no spirochætes were seen in the deposit The Wassermann reaction gave a clear negative result

On May 3rd the patient was in a very collapsed state and only semi-conscious; intravenous saline injections containing sodium bicarbonate were given, adrenalin was also administered, but the patient gradually sank and died the following day A blood film taken two days before death showed hæmoglobin deficiency; the red cells showed alteration in shape and size, polychromasia was exhibited, although no basophilic degeneration was noticed; platelets were few. The white cells showed vacuolation and fraying of the nuclear material.

Discussion

It is to be remarked that the symptoms shown in this case were not quite classical. At no time was there any great rise of temperature, 99° being the highest, and in point of fact the temperature was subnormal The patient had the usual slow pulse and the symptoms gradually deepened from a catarrhal to a grave toxæmic type of jaundice There was no glandular swelling, but hæmatemesis with semicoma were the salient features of the last phase. It is somewhat important to observe that even at an early stage there was variability in the size, shape, and staining qualities of the red cells that many cells appeared frayed, and hæmoglobin was deficient. The leucocytes also showed variable staining qualities as well as evidence of degenerative changes



Spirochætes seen in film of blood.

It is well known that rats are carriers of this disease, their urine, teeming with spirochætes can contaminate food and drink and that this is the usual source of infection for human beings It was noted that there were rats in the ships in which the patient made the journey to England.

Authorities state that the spirochætes may be observed in the peripheral blood till the fifth or even the seventh day by dark-ground illumination. By inoculation of the patient's blood (till the seventh day) into a guinea-pig the animal develops albuminuria and jaundice and the spirochætes will be found in its liver and blood After the seventh day the spirochætes are entirely absent from the blood, passing into the internal organs; between the ninth and fifteenth day they may be seen in the urine. Before death, however, in this case they appeared in the blood and also in the urine

A reproduction of a drawing is given to show the disposition of the spirochætes as they appeared in the film of the patient's blood.

I have not entered into details of all the therapeutic measures adopted during the illness which varied from time to time as the patient s condition demanded and included a strict diet of milk, citrated and otherwise, fruit juice, and bland fluids; irrigations containing a mixture of sodium bicarbonate and citrate, rectal injections of dextrose and starch, also injections of adrenalin and strychnine, inhalation of oxygen, &c

---

[1] Brit Med Jour. 1926, ii., 108

Conclusions

It appears to me that in all cases of jaundice, however mild, examination of the blood for spirochætes should be a routine measure Should they not be found the blood cells should be examined for degenerative changes, and if these be present, then the agglutination test with stock spirochætes should be performed at once, if this is found positive the antiserum for this disease should be injected without delay This treatment has been found wonderfully effective in the early stages of the disease

A CASE OF MENINGITIS

DUE TO THE TUBERCLE BACILLUS AND A DIPLOCOCCUS CLOSELY ALLIED TO MICROCOCCUS TETRAGENES

BY J TODESCO, M D FLORENCE, M R C S ENG, D P H,

RESIDENT MEDICAL SUPERINTENDENT, BOROUGH HOSPITAL, CROYDON

THE following case is of interest on account of the findings in the cerebro-spinal fluid and the condition revealed at autopsy.

S M., a boy, aged 2, was admitted to the Croydon Borough Hospital on Oct 24th, 1926 He had previously suffered from measles, and, one month ago, from diarrhœa and vomiting There was a history of tuberculosis in both parents, the disease being active in the mother at the time of his admission A fortnight before he had become irritable and sleepy, on Oct 16th he was put to bed as he appeared worse and was feverish, and the day before admission he started having convulsions and became delirious with head retraction and rigidity of limbs and neck

On admission the child appeared semi-conscious, was flushed, and moaned constantly In addition to rigidity there were frequent twitchings of limbs The abdomen was not tender or wasted, *tache cérébrale* was marked The heart sounds were rapid and weak and there were some râles over both lungs, with rapid, though not laboured, breathing The pupils were dilated and fixed and there was some bilateral conjunctivitis and photophobia The right knee-jerk was increased, the left absent, and Kernig's and Babinski's signs were markedly positive on both sides He had constipation and some difficulty of swallowing Temperature 100 8° F on admission On lumbar puncture the cerebro-spinal fluid was slightly turbid, but not under pressure On examination it contained a few lymphocytes and broken down polymorphs and a Gram-positive diplococcus, some in tetrad formation There was excess of fibrin in fluid

Lumbar puncture was repeated on Oct 25th, 26th, 27th, and 28th, amounts varying between 25 c cm and 30 c cm being withdrawn On two occasions there was increased pressure, and on the 28th the fluid withdrawn was clear The Gram-positive diplococcus was present on each occasion and it was also recovered from the blood on culture Tubercle bacilli were not at first found in the cerebro-spinal fluid, but were present in the fluid withdrawn on Oct 26th

After the first lumbar puncture the child was quieter and there was less rigidity and head retraction He had profuse general sweating at times He appeared to improve slightly until Oct 28th when he became less conscious, the rigidity increased, and there were also twitchings of limbs and teeth-grinding Cheyne Stokes breathing was now observed and greater difficulty of swallowing In addition there was retention of urine and diarrhœa His condition grew steadily worse and he died on Oct 29th in coma The temperature kept persistently high throughout being between 100° and 103° and reaching above 104° on two occasions The pulse was always rapid and weak and could not be counted at times, and the respiration rate varied from 14 to 70

Post-mortem Findings —Brain Excess of cerebro spinal fluid in ventricles Extensive gelatinous yellow infiltration of membranes along whole of under surface extending along fissures of brain On the vertex the whole of the right cerebral hemisphere was dotted with small yellow abscesses, but none were present over left hemisphere Petrous bones were healthy Thorax A few caseating glands along bronchi, no free fluid in pleural cavities Both lungs partially collapsed and studded throughout with miliary tubercles no consolidation present, diaphragm normal Pericardium contained about 1 oz of clear yellow fluid, heart appeared normal. Abdomen No free fluid or enlarged glands found anywhere The intestines were normal, the liver slightly enlarged, and the spleen contained miliary tubercles throughout Both kidneys showed some cloudy swelling, but no tubercles

Cultures were taken from the right hemisphere spleen, lungs, and pericardial fluid, and in each case a diplococcus similar to that present in the cerebro-spinal fluid was recovered

The following were the cultural characters of the organism isolated from cerebro-spinal fluid and blood (intra vitam) and organs (*a*) On agar slope after 24 hours' incubation thin porcelain-like smooth growth with crenated margin (*b*) On gelatine stab after 24 hours incubation fine white growth, no gas, some liquefaction (*c*) Sugars lactose, no change, glucose, acid, milk, alkaline (*d*) Staining The organism was Gram-positive and was a diplococcus, arranged in pairs, also in tetrad formation It appeared to be closely allied to the *Micrococcus tetragenes*, but in cultural characters resembled the *M liquefaciens* rather than *tetragenes* (*e*) The organism had no effect on two mice given 0 25 c cm and 0 5 c cm of a broth culture thus differing from the *M tetragenes*, which is pathogenic to mice causing a septicæmia

Discussion

The points of interest in this case appear to be (1) The character of the cerebro-spinal fluid, which in addition to containing tubercle bacilli, contained a diplococcus and was turbid instead of clear as is usual in tuberculous meningitis (2) The cultural characters of the organism, which, though on microscopical examination it appeared like a true *Micrococcus tetragenes*, differed from it on culture and in being non-pathogenic to mice (3) The post-mortem findings The lesions of the right cerebral hemisphere were not suggestive of tubercle and, moreover the diplococcus was recovered on culture from this organ, the spleen, lungs, and pericardial fluid

It appears that the child died from a mixed septicæmia due both to the tubercle bacillus and to a diplococcus recovered from the cerebro-spinal fluid, blood, and various organs Though *M tetragenes*, which the organism closely resembles, is found in suppurative lesions and in the respiratory tract in man, it does not usually cause a septicæmia in human beings

I wish to thank Dr H P Newsholme, medical officer of health for Croydon, for permission to publish this case, and Prof J C Ledingham, F R S, of the Lister Institute, for his help and confirmation of the bacteriological findings, and for applying inoculation tests

---

ROYAL MEDICAL BENEVOLENT FUND —The hon treasurer of the Fund gratefully acknowledges the sum of £30 from Dr (Phil) Otto Rank of Vienna, per Dr Marie Moralt

At the last meeting of the Committee 44 cases were considered and £769 13*s* 6*d* voted to 40 applicants The following is a summary of some of the cases relieved —

Widow, aged 65, of L R C P Edin who practised in London and died in 1919 Applicant has worked as a deaconess for years until August last, when she had to give up on account of leg trouble Total income £90 per annum Rent 11*s* a week Voted £26 in 12 monthly instalments

Widow, aged 45, of M R C S who died in November Left with girl of 14 and boy of 12 No private income and only £100 from Insurance Has had £150 from mother in law but it is uncertain whether this will be continued Now lives in three rooms at a rental of 12*s* a week Voted £20

Widow, aged 53, of M D who died in December last Left with six children ages 11 to 21 Only the eldest one earning One son studying for the law Others at school Voted £30

M D, aged 83 Married one daughter aged 40 Owing to financial losses had to take up practice again Receipts do not meet expenses £200 only received this year Private income £100 Rent £117 Voted £40 in 12 monthly instalments

Daughter, aged 68, of M R C S who died in 1881 Owing to bad health is unable to earn much Only made £6 by fancy work £30 per annum from Yorkshire Medical Society Few small gifts from friends Rent paid by a friend Voted £26 in 12 monthly instalments

M R C S, aged 73, married, three children Has had to give up work on account of old age and deafness Wife has a post in a school Children are unable to help in any way Applicant has just lost an allowance of 10s a week through death of a sister Has the old age pension Voted £10 in 12 monthly instalments

L R C P Edin, aged 47, married, one daughter Receives £300 a year as an assistant Was taken ill and had an operation for appendicitis Now only able to do light duty and has to pay locum to do night work Asks the Fund to help with extra expenses connected with his illness Voted £35

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos street, Cavendish-square, London, W 1

Medical Societies.

ROYAL SOCIETY OF MEDICINE

COMBINED MEETING OF THE SECTIONS OF TROPICAL DISEASES, DERMATOLOGY, AND THERAPEUTICS

THE TREATMENT OF LEPROSY

AT the combined meeting held on Feb 2nd a discussion took place on the treatment of leprosy Prof R T LEIPER, F R S, President of the Section of Tropical Diseases, took the chair

Dr J M H **MACLEOD** said that conditions obtaining in the St Giles's Homes for British Lepers gave an excellent opportunity of appreciating the value of different forms of treatment, especially as the patients, many of whom were well educated, were able to cooperate in efforts on their behalf Outstanding figures in the advances which had been made since 1909 were Rogers and Muir (Calcutta), Power, Dean and Macdonald (Hawaii), and Denny and Brill (Philippines) The tendency to remission of the disease made it necessary that any remedy should have a prolonged trial before being approved It was difficult to say that a case of leprosy was cured, as even after years of apparent freedom from the bacilli recurrence was liable to take place It was now generally recognised that the disease tended to be self-curative, but the process involved long years of suffering which left many mutilations

Treatment might be either general, local, or specific It was impossible to exaggerate the importance of placing the patient under the best hygienic conditions with ample good food and a cheerful environment The patients seemed to do best in high dry altitudes, summer usually brought improvement and winter relapses Local treatment was palliative and symptomatic and had but little influence on the general course, freezing of isolated nodules with carbon dioxide should not be done without great caution Specific treatment included the use of (1) metallic preparations, (2) sera and vaccines, and (3) certain oils and their derivatives Little could be said for arsenic and mercury (either perchloride or sozoiodolate), but benefit had been attributed to intramuscular injection of tartar emetic or colloidal antimony, the latter being preferable because it caused little irritation and had practically no toxic effect Iodide of potassium had also been employed either alone or with chaulmoogra oil, and had brought about flattening of nodules and healing of ulcers Sera had not so far been of value in the disease Koch's tuberculin produced a strong reaction in leprous patients In some cases this was followed by temporary improvement, but in others by intensification of the disease, and its use had the additional risk that it might light up latent tuberculous foci, since leprous patients frequently had both diseases Benefit had been claimed from the use of non-specific vaccines prepared from *B typhosus* staphylococcus and *B pyocyaneus*, which produced a reaction, but similar effects followed the injection of milk-albumin It was the general experience that patients benefited by the use of vegetable oils and their derivatives in direct proportion to the quantity tolerated Sir Leonard Rogers had shown that unpleasant drawbacks due to the oil could be obviated by substituting either salts or esters of their fatty acids these being given by injection Dr MacLeod still preserved an open mind about the specific action of these remedies

Dr **ERNEST MUIR** (Calcutta) contributed a paper, which was read by SIR **LEONARD ROGERS**, F R S Dr Muir agreed that there was not yet any real specific for leprosy but submitted that by following a certain line of treatment all active signs of the disease could be made to disappear permanently in early cases, though there was liability to relapse if the general health was markedly lowered. In Calcutta treatment was being carried out on the following general lines. (1) treatment of any accompanying physical or mental disease; (2) rectification of diet; (3) exercises, gradually increased in extent, and (4) use of special drugs, chiefly hydnocarpus oil and its preparations The routine he said was to begin with injections of hydnocarpus oil with 4 per cent creosote, either intramuscularly or by infiltration under the skin of extensor surfaces These injections were given twice weekly, beginning with 4 c cm. and gradually rising to 10 c cm When the latter dose was well tolerated a solution of sodium hydnocarpate in saline (1 per cent) was given intravenously twice a week, beginning with 2 or 4 c cm and rising to 10 c cm This treatment was continued until reaction followed or the veins became blocked; in either event infiltration with oil was resumed In the second stage of the disease care must be taken to avoid untoward results, only small injections being given until the patient had been brought into a good general state In the third stage treatment could be pressed without fear

Three classes of agents broke down lepra cells: (*a*) acute fevers (malaria, kala-azar), streptococcal and staphylococcal infections; (*b*) anything which produced protein shock, (*c*) the injection of irritating substances Vaccines, especially when used intravenously, were very useful in the third stage of leprosy Treatment should be persisted in for from six months to two years after all active signs of the disease had been absent

Dr H W **WADE** and Dr C B **LARA** (Culion Leper Colony, Philippines) sent a contribution which was read by Sir Leonard Rogers They said that the antileprosy campaign in the Philippines at the present time was a three-phase one in which both treatment and segregation played leading rôles The chief medicament employed by them was chaulmoogra ethyl esters, usually with iodine added to reduce irritation Weekly intramuscular injections were used almost invariably. At the San Lazaro Hospital in the five years 1921–25 a total of 250 bacteriologically positive cases had become negative This was largely a collecting-station and could not accommodate all the patients who were eligible to stay. In the Cebu detention camp (where treatment was even less than at San Lazaro) there was a large turnover of cases At the Culion colony new work was started in 1921 with 500 cases, and by early in the following year 1000 cases were under treatment—*almost exclusively* by ethyl esters—while by the end of that year the cases that had been for a time under treatment totalled 4458, the average duration of the disease in these being about eight years Up to Nov 1st last 358 patients had been discharged or paroled 27 had died while in the negative period, and on that date 244 negatives were under observation Of the 358 cases that had now been sent out only four had returned to Culion and three out of 245 paroled For work on a large scale the modern *treatment* was decidedly superior to the older, especially in early cases

Dr **ISABEL KERR** (Dichpalli Leper Institution, India) sent a paper of which the substance was given by Sir Leonard Rogers At this institution treatment began with the ethyl ester of the fatty acids of hydnocarpus oil combined with creosote camphor and olive oil these being given subcutaneously or intramuscularly Following this treatment insensitive patches improved nodules disappeared, and the patient's condition markedly improved. Later the pure ester was given combined with iodine intravenously and intramuscularly, in this way as much as 16 c cm of ester was given to some patients in a week and the early cases which could tolerate such a dosage did well Acute skin cases rarely took the full dosage Sixty-six per cent of cases were very much improved, while 12 per cent had become symptom-free They felt that in early cases, they could depend on a large percentage of successes: in the second stage only small doses must be given owing to the danger of aggravating the disease; in the third stage the drug could be pushed.

Dr J H **SEQUEIRA** referred to the case of a patient with advanced maculo-anæsthetic leprosy, a European, aged 44, who was given an injection of 100 c cm of a sterile saline solution Within half an hour of the injection he had rigors and the temperature rose to 100° F A few days later he was given a similar injection, and it was again followed by a rigor and the temperature was 101° After this second injection the leprous eruption began to fade A third similar injection resulted in a rigor and a temperature of 100 4° Thereafter the lesions had disappeared and during the following 16 years had not recurred

Dr. G **PERNET** said that he had found that the best treatment of leprosy in the nodular form was chaulmoogra oil, but it must not be looked upon as in any sense a specific Those who undertook treatment of this disease must remember how remarkably the bacilli were generalised throughout the body He emphasised the importance of hygiene, good food, and fresh air, and suggested the use of thyroid extract because it increased general metabolism

Dr G C **LOW** agreed there was not yet available any specific cure for leprosy, but urged that the work being done on the subject, apparently with a considerable measure of success, should be persisted in

Mr T A **HENRY**, D Sc (Wellcome Chemical Research Laboratories) said that it was thought by chemists that the beneficial action of chaulmoogra and hydnocarpus oils in leprosy was due to chaulmoogric acid and hydnocarpic acid, which were now being administered in the form of sodium salts, ethyl esters, or carefully refined natural oils Sir Leonard Rogers had pointed out that in order to be useful the acids must be employed in the liquid state, or nearly so, at the body temperature A mixture of the two acids gave the best results, and American workers had been so impressed with this fact that they were importing the seeds of the various trees for cultivation in their own country Research had shown that mercury, gold, and copper compounds appeared occasionally to exert a favourable influence on both tuberculosis and leprosy. Most hope seemed to centre round the mercury derivatives

Dr **ROBERT COCHRANE** spoke of his experiences in connexion with the Mission to Lepers He remarked that hydnocarpus oil with 4 per cent creosote was now the cheapest of the remedies

Dr E A O **TRAVERS** gave an account of his work as physician at the Qualalumpore establishment in the Federated Malay States There the main treatment was by the powdered whole nut of the hydnocarpus Of his cases 81 per cent were improved and 11 5 per cent became negative under the treatment, while the improvement in the general health of most of the patients was remarkable The remedy was taken by the mouth twice daily, and was popular Injections were given in addition when a case did not seem to respond well

Dr **JAMES HASSON** said he had found chaulmoogra disappointing, but most of his cases had the disease in an advanced form He did not agree that the results of treatment by vaccines were due to protein shock, he thought that the action of vaccines was specific

Dr F. **HALL** spoke of his work of ten years at Fiji Leper Asylum The tendency of leprosy, he said, was towards cure if cases came under care and were given the best conditions early Intercurrent diseases must be carefully treated in every case

Sir **LEONARD ROGERS** said that though a 3 per cent solution of sodium salts of the oils caused irritation in some patients, it did not do so in all, and he had found that a small vein would stand six injections of a 1 per cent solution without pain, and that here was no precipitation in the vein The cost was five doses for a penny Moreover, the 1 per cent solution was as beneficial as the 3 per cent Recent researches showed that the situation was now much more hopeful Leprosy was largely a question of house infection and means were at hand to reduce the disease to very small dimensions in two or three decades In South Africa early sufferers were seeking to enter the sanatoria —a welcome change in the public point of view He concluded by paying a warm tribute to the work being done in this matter by the Americans

---

MEDICAL SOCIETY OF LONDON

AT a meeting of this Society held on Feb 7th, Sir **HUMPHRY ROLLESTON**, the President, in the chair, Dr F M R **WALSHE** opened a discussion on

POLIOMYELITIS.

His paper appears in full on p 326 of this issue

Prof **JAMES McINTOSH** gave a summary of the experimental work which had been done on the ætiology and pathology of the disease Acute anterior poliomyelitis, he said, was now a very clearly defined disease at the stage at which the paralytic symptoms had developed Knowledge of its pathology was comparatively recent It had been placed on a sound basis by the monographs of Harbitz and Vickman (in connexion with the Swedish epidemics) and by Muller, Lansteiner, Levaditi, and others In postmortem examinations of acute cases of the disease evidence was found of a toxæmia, mild degeneration of internal organs was found, and general enlargement of lymphatic glands, including those of the intestinal canal In the central nervous system, and especially in the cord, there were minute hæmorrhages and congestion of the grey matter Lesions of the central nervous system were practically confined to the grey matter of the cord; only rarely were there marked lesions in the cortex There was definite involvement of the pia-arachnoid, particularly of the perivascular type—i e, in the perivascular lymphatic sheath of the blood-vessels of the cord The pia-arachnoid was found to be densely packed with cells In the anterior horn of the grey matter of the cord there was an intense inflammatory reaction, with minute hæmorrhages and destruction of the ganglion-cells Later these were removed by the phagocytic cells The main cells found were lymphocytes, but there was also a small number of the larger endothelial leucocytes, and some polynuclear leucocytes, and sometimes plasma-cells The chief lesion of the cord was a degeneration of ganglion-cells, followed later by complete disappearance of the cells—hence the anæsthesia and the complete paralysis which developed Softening of the cord occurred only in rare cases Histological findings confirmed the conclusion arrived at earlier on clinical grounds that this disease was an acute infection

In 1909 Lansteiner and Kocher, working in Vienna, had succeeded, for the first time in transmitting the disease to monkeys, they took the spinal cord from a fatal case of the disease, ossified it in saline, and injected it into two monkeys by the intracerebral route, following a trephine opening, 1 c cm of the fluid was injected and the monkeys developed the disease 16 to 18 days respectively after the injection, and had paralysis of the lower limbs One of them died of the disease, and the lesion found in its cord was absolutely identical with that found in human cases Confirmation of this had since come from practically every civilised country In 1912 and 1918 Prof H M Turnbull and the speaker had successfully done the same inoculation It was not so easy to transmit the disease to rabbits

The Incubation Period and the Virus

It was always difficult to work out incubation periods of human infections, but work on monkeys showed an incubation period varying between 4 and 17 days, it worked out in a number of cases at 9 to 10 days In the Swedish epidemic the period was 14 to 16 days The monkey when given the disease showed prodromal symptoms, was out of sorts, and lost relish for food, it had tremor of limbs and the temperature was raised In from 24 to 48 hours paralyses suddenly supervened, commencing usually in the lower limbs and thence extending upwards. In the monkey, in most instances, the disease was fatal In a few it was mild and transient and recovery was quick Investigations on monkeys showed that the responsible virus was a filter-passer; it could even pass through some of the coarser porcelain filters For that reason it had not yet been cultivated. The research revealed the curious fact that the virus had some extraordinary powers of resistance. An infected cord could be completely dried over caustic soda and yet would remain virulent for 24 days; it could be kept in ice indefinitely, or frozen, without its virulence being thereby diminished Even a 50 per cent. dilution of glycerine had no lethal effect on the virus which also showed a special resistance to antiseptics, apparently 5 per cent carbolic had no effect on it On the other hand, it was very susceptible to a 1 in 1000 solution of potassium permanganate, which killed it at once Hydrogen peroxide was in the same category This was important as it affected prophylactic measures directed to the nasopharynx. The question of the distribution of the virus in the body had been worked at chiefly by inoculating monkeys with the organs of monkeys which had the disease or with the organs of human beings who had died of the disease In the monkey disease wherever the inoculation was made—brain, peritoneum skin nerve—the result and the succession of symptoms was the same being chiefly due to a cord lesion This demonstrated an extraordinarily selective action on the spinal cord The blood very rarely contained the virus nor did the spleen liver or kidneys It had been discovered only in the central nervous system and the lymphatic system

Mode of Spread

Vickman had attributed one outbreak in Sweden to contamination by milk continued Prof. McIntosh, and many patients suffered from gastro-intestinal disorder. It was not however, easy to give the disease to monkeys by infecting their food The common portal of entry of the virus seemed to be the nasopharynx Plugging the nasal cavity of the animals with infected material sometimes succeeded, but it was evident that the mucous membrane there offered some resistance This was generally overcome by abrading its surface The spread of the disease by excretions and secretions had also been investigated Vickman in 1905, had brought forward evidence of its spread by means of carriers, also by drawings and books There had not yet been any satisfactory evidence that bites of insects played any part in disseminating the disease It seemed to be mainly spread by direct contact—i.e., by contamination by the saliva and by coughing The nasopharyngeal mucus had been shown by Kling to contain the virus for many weeks after an attack of the disease Patients who had recovered from one attack remained immune for the rest of their lives· monkeys which had recovered from an attack even if abortive, could not again be inoculated with the disease and their serum was found to have antibacterial properties This had been the basis of attempted serum therapy, and good results were claimed for such treatment in France and America The quick onset of the disease was however a practical difficulty. Experimental attempts had been made to immunise monkeys by vaccination, either by means of a killed virus or an attenuated living one, and there had been some success As regards general measures of prophylaxis every effort should be made to keep the nasopharynx as free as possible from infection. As the virus remained in the throat for some time after the disease had apparently subsided cases should be isolated for about three weeks Estimates of the prophylactic value of serum must rest on future experiment In the face of a big epidemic the speaker did not see why attempts to vaccinate with the killed virus should not be made He concluded by pointing out possible diagnostic errors especially in regard to progressive muscular atrophy of the infantile type, Landry's paralysis and forms of toxic neuritis

Discussion.

SIR THOMAS HORDER said that Dr Mervyn Gordon, whom illness prevented from being present, had sent him a communication in which he said that the characteristic lesions in poliomyelitis were two—the condition termed neuronolysis and that named neuronophagia Thus there were the perivascular infiltrative lesions, which were not so peculiar to this disease and the more purely nervous specific lesions involving the cells of the grey matter

Sir Thomas Horder then spoke of the differential diagnosis of poliomyelitis from other acute infections which had little or no specific effect on the central nervous system. He said that pneumonia and especially the broncho-pneumonia of children, might resemble poliomyelitis when the subarachnoid was involved, and that in any case the possibility of encephalitis and infective polyneuritis must also be carefully borne in mind Three times he had seen retention of urine as the first symptom in poliomyelitis, all three patients being young adults Focal pains at the onset of the illness were significant, and should arouse suspicion. Generalised and especially local or focal tenderness and sensory disturbance he placed in the same category. Hexamine in full doses at the earliest possible moment seemed a likely mode of treatment; he had also given salicylate of soda intravenously morning and evening for three to six days In this disease the virus was a filter-passer, and he suggested there was an affinity between groups of infecting agents and drugs He had also given as early as possible, collosol iodine intravenously.

Dr. JAMES COLLIER said that the finding of the virus in the mouth of a person 17 days after an attack did not mean that that person was capable of infecting a fresh patient with the disease. He related a number of facts which had strengthened his belief that this was a disease which was disseminated by non-suffering carrier cases

Dr. A. F. HURST dealt with the administration of hexamine in the disease He believed that the reason it had not given uniformly good results was that the doses given were not large enough; 10 even 20 gr. thrice daily was not nearly enough. If 60 gr. each of potassium citrate and sodium bicarbonate were given at the same time 100 gr. of hexamine could safely be given thrice daily without any anxiety about the urine He had not carried out this treatment in poliomyelitis but he had in encephalitis and it was easily borne by the patients

Dr. H. M. RAVEN spoke as a patient who had recovered from the disease and gave an account of the Broadstairs visitation of poliomyelitis. There had been two or three cases at each of several schools, but half the epidemic had been in separate houses. From his observations and experience he could not consent to the idea that dust and flies could be left out of the agencies of spread During the epidemic he had found constipation very rife as well as some cases of suppression of urine He reminded members that macerated flies had been proved to be capable of infecting monkeys

Mr. R C ELMSLIE said that 30 per cent or more of the cases of past poliomyelitis which he saw as a surgeon had not been correctly diagnosed when they had the acute disease The brief febrile condition was apt to be unnoticed in little children. A large number of cases were not part of epidemics, but isolated cases Often the diagnosis had to be made from some form of arthritis of the hip-joint. Two or three years ago he with others had interested himself in the matter and had got the London County Council to agree to set aside a certain number of beds for segregating cases of poliomyelitis but the purpose had been largely spoiled by the decision that to these reserved beds no case could be admitted until three months had elapsed since the onset of the disease.

Dr WALSHE and Prof MCINTOSH very briefly replied

LIVERPOOL MEDICAL INSTITUTION

A meeting of this Institution was held on Jan. 13th, when Prof. D. P. D. Wilkie read a paper on the

Place of Surgery in Treatment of Diseases Associated with Enlargement of the Spleen

Until quite recent times, he said, the interest of surgeons in the spleen had centred mainly in the operative treatment of traumatic rupture of the organ and in the rare cases of torsion of a wandering spleen. Increasing knowledge of its functions, and thus of the rôle which the spleen possibly played in diseases in which it was manifestly enlarged, had encouraged attempts to remove it in cases of splenomegaly. A phase of what was, in fact, experimental surgery had then set in, and the effect of splenectomy on the course of diseases associated with splenomegaly had been studied intensively.

The treatment of these diseases should involve constant and intimate coöperation between the physician and the surgeon. In cases of septic infarct of the spleen surgical interference was practically never necessary, the special surgical interest of these cases lying in the likelihood of their being mistaken for a perforation needing immediate operation. In cases of splenic tuberculosis the question of splenectomy should be thoroughly discussed, for it had been found that in certain cases removal of the organ had led to a favourable termination of a long febrile illness. With regard to syphilis, Mayo had first drawn attention to the fact that the spleen might be the fastness in which the spirochæte could lodge and defy all specific drug treatment, and had shown that splenectomy would permit of rapid cure by medicinal means. Operation for splenic anæmia or Banti's disease presented two main difficulties. In some cases extensive and dense perisplenic adhesions might hamper removal, so that in freeing the spleen there might be considerable hæmorrhage and shock. The second difficulty lay with the splenic vein, which was friable from endophlebitis and might tear when ligatured. Special care would obviate this complication. When operation was performed in the late stage of the disease in the presence of hepatic cirrhosis and ascites the combination of omentopexy with splenectomy, as advised by Tansini, appeared rational and had been performed with success in a number of cases.

In diseases of the blood associated with splenomegaly, went on Prof. Wilkie, pride of place should be given to hæmolytic jaundice, for of all the blood dyscrasias with splenic enlargement it was most often successfully treated by splenectomy. The relief following operation in this condition was so dramatic as to be almost unbelievable. There was only one treatment for hæmolytic jaundice and that was splenectomy. It presented no special difficulties in this disease, and extirpation of the organ which was responsible for breaking up and destroying the fragile red cells was immediately followed by the disappearance of all signs and symptoms of the disease.

After discussing other conditions in which the spleen was enlarged Prof. Wilkie concluded by stating that splenectomy had now an established place in the treatment of acquired hæmolytic jaundice, chronic purpura, splenic anæmia, and Gaucher's disease. In certain other diseases it might be carried out with benefit in a few selected cases—namely, in splenomedullary leukæmia, pernicious anæmia, Jaksch's disease, and tuberculous and syphilitic splenomegaly. In a third group of diseases such as malaria, polycythæmia vera and the acute leukæmias, the operation was not indicated.

Dr. S. W. Patterson read a paper dealing especially with the medical aspects of the subject. By radiography, he said, the spleen could be demonstrated (*a*) directly, and also (*b*) indirectly by the deformity of the greater curvature of the stomach or splenic fixture of the colon when these organs were distended with opaque material. He agreed that in cases of acholuric jaundice splenectomy was the treatment of choice, and illustrated the familiar type of these diseases by describing a family of 29 members. Of this family, 17 members were affected and eight of them had had the spleen removed. The operation had brought about immediate relief of the jaundice and lessening of the anæmia, but the fragility of the red blood corpuscles was apparently unaltered, and in one case it was present 18 years after splenectomy. In pernicious anæmia the results of splenectomy were not good, but in purpura depending on a dyscrasia of the blood platelets the operation gave satisfactory results. He emphasised the good results of X ray treatment of spleen and long bones in leukæmia, and concluded by saying that, although the spleen was far from being a superfluous organ, the normal spleen could be removed without seriously injuring health. A spleen acting abnormally was a dangerous organ and was better taken away.

CARDIFF MEDICAL SOCIETY.

At a meeting of this Society held on Jan. 18th, Dr. Alfred Howell in the chair, Prof. E. H. Kettle read a paper entitled

The Story of Experimental Cancer Research

The systematic experimental investigation of cancer, he said, dates from the publication of Jensen's papers in 1902-03, in which was announced the successful propagation of a mammary carcinoma of the mouse through many generations. Jensen's tumour was exhaustively studied in this country and on the continent, and very soon other spontaneous tumours in mice and rats were recognised and made available for further study. Much information about the general biology of malignant tumours and the special features of individual examples was gradually accumulated, but it has become recognised that the study of propagated tumours is only of limited value. In any series of inoculations tumours fail to grow in a certain proportion of the animals. Further, some tumours after a period of progressive growth retrogress and finally become completely absorbed, when the mice in which this has occurred become refractory to further inoculations with the same brand of tumour. These observations fitted in well with the current trend of pathological thought, and the investigation of natural and acquired immunity to the inoculated tumour was entered upon with high hopes. Unfortunately, though mice can be rendered immune to inoculation with tumour tissue, no means has been discovered to control the progress of spontaneous tumours.

About this time, when it seemed that experimental cancer research had reached a dead end, it received a welcome stimulus in the work of certain Japanese investigators, who demonstrated the possibility of producing cancer of the skin in animals by exposing them to irritants, especially tar. This line of research has been fruitful in results and has still great possibilities. It has been shown, for example, that as a general rule cancer of the skin can only be produced by the repeated action of the irritant and develops only after a considerable period of time, a period corresponding to some 20 or 30 years in the life of man. At the same time it is not necessary to apply the irritant throughout the whole of this period; a couple of months' application of tar may be followed four months or more afterwards by the development of cancer. Of even greater significance in their bearing on human pathology are certain observations that tend to prove that a local cancer is associated with a definite constitutional change.

After referring to the study of the cancer cell in cultures in vitro, Prof. Kettle briefly dealt with the recent work of Gye and Barnard. He pointed out that all the work of the past showed that, with one exception, malignant growth could only be propagated by the inoculation of the actual living cell. This exception was the sarcoma of fowls described and studied by Peyton Rous, which could be propagated by a cell-free extract Gye has demonstrated that this cell-free extract contains two substances neither of which is capable of producing a *tumour* when used alone though in combination they can do so. Gye claims that one of these factors is a non-specific living virus and on the optical side he is supported by Barnard's work This work is still very recent but it has received already a considerable degree of confirmation and is obviously of the first importance Indeed its bearing on the general problem of infection may eventually outshadow its application to the more limited pathology of tumours

ABERDEEN MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society held on Jan 13th Dr **THOMAS FRASER** Vice-President, in the chair Dr. **ROBERT RICHARDS** read a note on

Some Cases of Dysentery in Aberdeen

Bacillary dysentery, he said was classified under three main headings. (1) endemic occurring in tropical and subtropical countries (2) epidemic usually occurring in the minor form in local outbreaks in this country, and (3) sporadic, occurring in strictly isolated cases where the two previous types were rare or unknown Referring to the work done on infantile diarrhœa and the differences of opinion about the causal organisms Dr. Richards said that American investigators had found that in a large proportion the *Bacillus dysenteriæ* of Flexner was responsible, the proportion found at the Boston Floating Hospital being 75 per cent and at Baltimore 80 per cent. The latest figures for Britain were those of D. Nabarro who had found dysentery bacilli in 13 cases out of 150 treated at the Hospital for Sick Children, Great Ormond-street In the Aberdeen epidemic the first case recorded had been that of a boy aged 7, sent to the Royal Hospital for Sick Children with a diagnosis of intussusception.

He had been ill for two days with vomiting purging, and fever (101 2° F) with the passage of large quantities of blood and mucus On admission he had a pinched, anxious expression the abdomen was retracted and tender, but no tumour was felt Rectal examination caused severe tenesmus with the expulsion of some blood and mucus A tentative diagnosis of ileocolitis or dysentery was made, but in view of the doctor's statement that he had felt a tumour the abdomen was opened No tumour was found, but the colon was thickened and swollen, and the appendix swollen and congested with great enlargement of the mesenteric glands The case was then treated as one of acute dysentery, and the condition rapidly cleared up on administration of magnesium sulphate. The finding of *B dysenteriæ* (Flexner) confirmed the diagnosis.

In this country, said Dr. Richards the diagnosis of intussusception in such cases was not unlikely, but on rectal examination a distinct difference was to be made out In dysentery the tenesmus set up was very great and the examining finger was forcibly ejected followed by the passage of blood and mucus; in intussusception, on the other hand, the rectum was large and roomy—unless a tumour was felt—and no tenesmus was set up

The next three cases described were children aged 8, 4, and 5, all of whom showed typical symptoms of dysentery *B dysenteriæ* (Flexner) had been isolated in two of the cases; examination of the stool in the remaining case had twice been negative for dysentery organisms but this might have been due to delay in transmitting the specimen In the fifth case that of a child of 4, there had been practically the same symptoms but the causative organisms had belonged to the food poisoning group, the *Bacillus aertrycke* An interesting feature of this case was a sequela three years later, when the patient came up complaining of a painful left knee, the pain being evidently referred from the hip-joint where all movements were restricted and a certain degree of fixed flexion was present The temperature was 100° and the pulse correspondingly rapid. Radiographic examination was negative On the same afternoon the patient became sick and developed diarrhœa accompanied by tenesmus and the passage of blood and mucus in the stool A diagnosis of dysentery with toxic arthritis was made and the finding of the Sonne bacillus confirmed this Further confirmation was afforded by the clearing up of both conditions under treatment with saline aperients Dr. Richards said that he believed that there was no previous record of such metastatic joint symptoms from Sonne dysentery although arthritis was a common complication of both Shiga and Flexner dysentery in Macedonia. After describing a further series of three cases of Sonne dysentery he gave it as his opinion that true dysentery was not so rare amongst the general population as was usually stated Treatment with magnesium sulphate was found to be almost specific

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE

A **MEETING** of this Section was held on Jan 28th, Dr G E **NESBITT** the President in the chair

Dr. **MAURICE DRUMMOND** showed three cases of

Ringworm in Children treated by Epilation with Thallium Acetate

The children were aged 6, 4 and 2 years and 5 months The method, said Dr Drummond, had been used successfully in over 500 cases by Cicero and Peter in ringworm schools in Mexico and in over 100 cases by Buschke and Langer in the Rudolph Virchow Hospital in Berlin It was essential that one alone of the salts of thallium should be used—the protoxide of the acetate of thallium. He had used that of Kahlbaum The Germans found that 8 mg. per kg. of body-weight was the most satisfactory dose for children of all ages Peter in Mexico gave 5 mg per kg for children under 5 years of age In each of the children shown 8 mg. had been administered and Dr. Drummond had found it only just sufficient in the case of the two younger children The drug was given in 2 ounces of sweetened water. Rapid and profuse fall of the hair took place on the fifteenth day with the two younger children The fall had not been so satisfactory with the eldest child. The action of the drug was apparently selective, the eyebrows and fringe on the front of the head being unaffected. As X ray epilation could not be carried out in children under the age of 3 he thought that—apart from its general utility—thallium epilation should be of especial value in young children as also in epidemics In the case of the eldest child who had been epilated in November, the hair was again growing well, and it was beginning to grow in the case of the second child who had been done in December. The youngest child had only just been epilated The drug was contra-indicated in the presence of albuminuria In case of partial failure, a further dose must on no account be given within at least two or three months, as the action of the drug was strongly cumulative and symptoms of acute poisoning might develop. Almost meticulous care was necessary in the weighing of the child and of the drug Dr Drummond was not yet sure that a slightly higher dose might not be necessary with older children Constitution climate, and the freshness of the drug were all factors to be considered

The **PRESIDENT** said that the effects of the treatment in the three cases shown were little short of miraculous. He regarded the method as much better than the use of X rays, but of course Dr. Drummond would require a larger experience of it before he could pronounce a final judgment on it

Dr E **FREEMAN** quoted a series of published cases.

Dr W. G **HARVEY** referred to the original experiments with thallium which had been carried out by Sabouraud, and which had been quite unsuccessful. Very large doses had been employed, and this, perhaps, had been the cause of the failure, as very serious symptoms had arisen after treatment including hæmorrhage and purpura This method now seemed to be of great use, quite apart from whether it would replace X ray treatment or not The difficulty of X raying young children, such as Dr. Drummond's patients was very great

After further discussion, Dr Drummond said that Langer in Berlin said that he got the thallium only from one chemist It was stated that the drug deteriorated with age If the drug was fresh, the hair would fall out on the fifteenth day after application, but if the drugs were not fresh when applied, the hair might take three weeks to fall out

Dr V. M SYNGE showed specimens from a case of

Spontaneous Hæmorrhage into the Brain

The specimens were from a young man aged 21 On Oct 14th, 1926, whilst at work he suddenly fell down unconscious He had previously been perfectly healthy and had received no injury of any sort When admitted to hospital a few hours later he was still unconscious, the limbs were rigid and flexed, and occasional clonic spasms occurred The neck was stiff Pulse rate 66, temperature, 99° F, respiration rate, 26 He vomited undigested food several times A catheter specimen of urine contained a fair amount of albumin The blood pressure was normal, and the blood urea 65 mg per 100 c cm

During the following days the temperature rose to 104°, the unconsciousness diminished On Oct 16th 30 c cm of fluid were removed by lumbar puncture It was under great tension and contained a good deal of blood There was no improvement after the puncture The Wassermann reaction of the blood was negative The patient remained semi-conscious, the neck stiffness increased, Kernig's sign was positive, and the limb was stiff but without paralysis On Oct 21st lumbar puncture was again performed, and 35 c cm of fluid under tension removed, the report being a little blood present (fluid otherwise clear) globulin slightly increased, glucose present, no pus, sterile on culture, and no tubercle bacilli present

A dose of 15 c cm of sodium salicylate solution was given intravenously, the high temperature, general condition, Kernig's sign, and character of cerebro-spinal fluid suggesting the probability of encephalitis lethargica The temperature dropped, the pulse rate fell from 100 to 60, but there was no improvement in the general condition The fundus of both eyes was normal The patient got suddenly convulsed, and on Oct 31st collapsed and died in a few hours

At *autopsy* there was no sign of any injury In the anterior horn of the right lateral ventricle there was a mass of clotted blood which had destroyed a large part of the frontal lobe, all the ventricles were full of blood, and there was a mass of effused blood on the base of the brain The heart, spleen, kidneys, and other organs were normal, there was no sign of arterial disease Sections failed to show any evidence of a tumour in the brain Sections of the kidneys were normal

This apparently quite spontaneous hæmorrhage, said Dr Synge, had evidently originated in the right frontal lobe, afterwards bursting into the ventricles and thence into the subarachnoid space

The PRESIDENT said that the case was very interesting, because in so young a patient no one would have thought of making a diagnosis of cerebral hæmorrhage, especially in the absence of the phenomena usually sought for Therefore the case was an important one He thought that the cause of spontaneous hæmorrhage was always difficult to ascertain It was possible to have fairly advanced renal disease with a blood-urea of no more than 65 mg, and he thought that in this case the boy probably had some chronic renal disease He asked if there was anything in the brain to suggest encephalitis lethargica He could not remember having seen cerebral hæmorrhage under the age of 29

SIR JAMES CRAIG said although in this case the blood-urea was greater than normal still the kidneys were healthy, therefore he did not think that it could be assumed that the hæmorrhage was due to any renal disease

Dr SYNGE, in replying, said that on account of the destruction done by the hæmorrhage it had not been possible to examine the artery that had actually ruptured The small arteries seen under the microscope appeared to be perfectly normal, and he thought that an artery was unlikely to rupture unless the pressure inside it was very great Nothing abnormal had been found in the kidneys, and there had been no evidence of nephritis at all, except albuminuria, which had been present at first It had been very difficult, however, to examine the urine as the patient had suffered from persistent incontinence.

Reviews and Notices of Books.

CÆSAREAN SECTION

With a Table of 120 Cases By HERBERT R SPENCER, M D., F R.C P., Consulting Obstetric Physician to University College Hospital London John Bale, Sons and Danielsson Pp 74 6s

Dr Spencer states that this little book makes no pretence to be a treatise on Cæsarean section, but is a record as frank as he can make it of his own experience of the operation He asks those who do not agree with his conclusions to publish a complete and detailed record bearing on the points of their disagreement The publication of a selected series of cases is deprecated, since a proper judgment as to the value of the statistics can only be formed when details are given, and also particulars of the number of craniotomies.

During the last 33 years he has operated on 120 cases, either in hospital or in private, with a maternal mortality and infant mortality-rate of 3 3 per cent and 10 per cent respectively The majority of these cases were derived from University College Hospital Maternity, where during this period over 80,000 labours were conducted He remarks that the small number of cases is partly due to the fact that at this hospital premature labour is induced three and a half times as often as Cæsarean section is performed for contracted pelvis A careful analysis is made of all the cases operated upon, full details being set forth in tabular form at the end of the book Contracted pelvis was an indication for the treatment in 81 6 per cent of cases, whilst 70 per cent were not in labour at the time of operation. The classical midline upper uterine segment incision was employed on all occasions, and the author states his reasons for not using the extra-peritoneal and trans-peritoneal cervical operations The operative technique is discussed in detail, and a strong plea is made for the use of carbolised silk in suturing the uterine incision, the author having abandoned the use of catgut more than 30 years ago

As to the anæsthetic employed, Dr Spencer insists on the use of chloroform until the child is delivered, and open ether subsequently Spinal anæsthesia is condemned, chiefly because the author believes it to be more dangerous than a general anæsthetic As the latter was given in all but one of his cases, this censure of spinal anæsthesia appears a little unwarranted, particularly as it has been employed by others on many occasions without a fatality The author also strongly disapproves of sterilisation of the patient after Cæsarean section and denounces this procedure in no uncertain terms We welcome this record of the personal experiences of a practised surgeon, which is a valuable addition to the literature of obstetrics

DIATHERMY

With Special Reference to Pneumonia Second edition By HARRY EATON STEWART, M D., formerly Attending Specialist in Physiotherapy, U S Marine Hospitals, New York, Consultant in Physiotherapy, U S V B Hospital, New Haven, Conn New York. Paul B Hoeber 1926 Pp 208 $3 00

THIS introduction to the medical and surgical uses of diathermy, with special reference to the treatment of pneumonia, has been increased by 18 pages in its second edition Additional instruction for the application of diathermy to the lungs of adults and children is given The author is now able to speak from experience gained in the treatment of 248 cases of pneumonia—more than three times the number which had been treated when the first edition of the book was published Nearly all have been cases of lobar pneumonia Particulars of 159 are given in tabular form Information is given regarding the number of lobes involved, the type of infecting organism, the day on which the treatment (by diathermy) was commenced, the number of applications and the dosage, the way in which the temperature fell, the immediate effects of the treatment, complications, and the final results of the treatment

The author describes in detail the effects of diathermy on the pulse-rate, respiration, temperature, blood pressure, and its influence on cyanosis and sweating He reviews critically the facts and figures when discussing the influence of the treatment on mortality. Details of a number of control cases are given A comparison of the results obtained by diathermo-therapy with those obtained by other methods of treatment seem to justify the conclusion that the death-rate in pneumonia was lowered when treatment by diathermy was instituted Although the mortality in some epidemics of pneumonia is extremely low, it is unlikely that this fact explains the excellence of the results obtained by the author and his co-workers over a period of five years The original series of cases treated by Dr Stewart were in patients in the U S Marine Hospital, New York The mortality, which was very high—viz , 42 9 per cent in the cases treated by other methods—was reduced to 17 1 per cent in those which were treated by his method A trial of diathermy in the treatment of pneumonia might well be made in this country

---

EUROPA YEAR-BOOK, 1927

Edited by MICHAEL FARBMAN, RAMSAY MUIR, HUGH F SPENDER London Europa Publishing Co , Ltd , 6, Duke-street, Adelphi, W C ; and George Routledge and Sons, Ltd With six coloured maps Pp 700 15s

THIS annual survey of economic and social conditions in Europe contains over 15,000 names of leading personalities in all the European countries, summarises the economic and social conditions prevailing at the moment, and provides a directory under the headings of politics, trade, science, art, and literature, in which a large number of biographical outlines will be found It is a successful attempt to give a brief but comprehensive exposition of the numberless subjects which fall within so huge a range, the main grounds for forming an opinion on vital comtemporary questions are furnished, and furnished with a real attempt both at impartiality and at setting down only such things as can be established by fact or fortified by argument It is certain that anyone intimately acquainted with, or expertly advised on, a particular section of activity would often find many gaps in the information supplied, but this may be regarded as due to a rigorous attempt to keep the various and varied material well balanced—an annual survey is not to be confused with an annual encyclopædia Medical men, for example, cannot consult the Europa Year Book in place of the Medical Register, or the Medical Directory, or the contemporary medical press, or the annual reports of the Minister of Health and the Registrar-General for specific or detailed information on particular points in the conduct of medical practice, or on the relations of medicine to the public, the usual sources of information and counsel must be gone to Similarly, members of other professions and callings will find that the sections under their respective professional headings are strictly circumscribed in content, not only for reasons of space, but also so as to preserve proper proportion in the compilation of a compendium Thus students of world affairs may not find an exact answer fitting any individual problem which has presented itself, but they will find fundamental facts with reference to it if it is a problem of vital contemporary interest, the associations, the persons or the literature from which they can obtain what they are seeking will be indicated, while a quantity of assorted facts will be at their disposal to assist them in making further inquiry The lists of learned persons and learned bodies, associations and institutions, may often seem incomplete, they are—but no such lists could ever include all that might seem satisfactory to every reader, while the really dangerous error of attributing distinction in the wrong place has been generally avoided

The publishers may be congratulated on providing at a reasonable figure and in convenient form just such a survey of the world's contemporary affairs as men and women with wide interests desire to have, whether to assist them along a special line or to give them opportunities for broader appreciations

---

BRIGHT'S DISEASE

Die Nephritiden und nichtentzundlichen Nierenerkrankungen By Prof Dr H STRAUSS Berlin Urban and Schwarzenberg 1926 Pp 400 M 21

THERE is no alteration in the general arrangement and scope of this, the fourth, edition of Prof Strauss's well-known monograph on Bright's disease The subject is treated from a practical point of view, and the book is especially valuable for the detailed directions which the author gives for the treatment of the various forms of Bright's disease in their several stages His simple classification of the clinical forms makes it easy for a practitioner to find information as to treatment of any particular patient under his care The author maintains a balanced point of view in handling the theories of the ætiology and pathology of Bright's disease The views held by well-known authorities, such as F. v Muller, Munk, Volhard, Fahr, Jores, and Aschoff, are concisely summarised, thus facilitating comparison not only of opinions, but also of nomenclature

The book is divided into two sections The first deals with diagnosis, and contains a good review of the subject of albuminuria, as well as a detailed description of the functional tests and the conclusions that may be drawn from them The classification of kidney diseases, their clinical pictures, and differential diagnosis also belong to this section The second section is devoted to therapeusis The various means of treatment are classified under the heading of causal and symptomatic treatment, the latter being further subdivided into physical, dietetic, medicinal, X ray, and surgical The application of these methods of treatment to the various forms of kidney disease and more important symptoms is then discussed. The book closes with a short chapter on the prevention of the disease, and a useful appendix gives the chemical analysis and calorie value of all foodstuffs and fluids in common use

STEVENS'S MEDICINE

The Practice of Medicine Second edition By A A STEVENS, A M , M D , Professor of Applied Therapeutics in the University of Pennsylvania London and Philadelphia · W B Saunders Company, Ltd 1926 Pp 1174 35s

WHEN Prof Stevens had been practising and teaching first pathology and then medicine for 30 years, he wrote a book, which now appears in its second edition only four years after publication In the first edition it was obvious that Prof Stevens had supplemented his extensive and mature experience by consulting the writings of many authorities, and the lists of references in the new edition show that he has spared himself no trouble in revision New articles include those on sickle-celled anæmia, Ayerza's disease, occlusion of the coronary arteries and lipodystrophy, while the advances made in recent years in our knowledge of diabetes jaundice, and diseases of the circulatory system are reflected in the appropriate sections Certain parts of the new material call for comment. For example, the description of Dick reaction for scarlet fever (p 237) leaves some confusion between its use for testing susceptibility and its use in the diagnosis of a scarlatiniform eruption

When dealing with nephritis, Prof Stevens sets out a good modern classification based on that of Volhard and Fahr (p 814) but he almost at once abandons this scheme and treats the subject on orthodox lines with a new note on "Epstein's nephrosis"

For the most part the claim that this book is "as nearly up to date as possible" is justified Thus in tuberculosis Prof Stevens makes it clear that inherited predisposition is not so important as was formerly believed and he stresses direct contagion as the dominating factor In the section on blood diseases it is satisfactory to find set out in full Sternberg's classification of the leukæmias as modified by MacCallum In the description of cerebral vascular disease the old-fashioned clear-cut distinction between hæmorrhage and thrombosis based on blood-pressure readings is swept away with the statement "in many cases a differentiation is impossible" although the application of this point to treatment is not clearly made Tabes dorsalis is dealt with on modern lines, but the early loss of the ankle-jerk rather than the knee-jerk should be stressed There is a very good account of thrombo-angiitis obliterans Such samples of many different sections of a large volume will serve to show that it contains a mass of good material and is worthy of a place in any medical library

---

Practical Physiological Chemistry

Ninth edition By Philip B Hawk, M S, Ph D, President of the Food Research Laboratories, Inc, New York City, and Olaf Bergheim, M S, Ph D, Assistant Professor of Physiological Chemistry in the University of Illinois, College of Medicine, Chicago London J and A Churchill 1926 Pp 931 28*s*

The previous issues of this work were from the pen of Prof Philip B Hawk, but this volume is under the dual authorship of Prof Hawk and Prof O Bergheim In the preface the original author pays warm tribute to Prof Bergheim for the par that he has played in the revision of the volume, and both authors are to be congratulated upon the excellence of their work The contents of the book are wide and varied, and the modern developments of the subject clearly and fully set out

In addition to bringing up to date all the original matter, seven new chapters have been added, dealing respectively with the physical chemistry of true and colloidal solutions, absorption, putrefaction and detoxication, the chemistry of the blood, respiratory metabolism and neutrality regulation, the endocrine organs and energy metabolism In the first chapter the physical chemistry of true and colloidal solutions and its application to physiological chemistry are discussed This is done in the space of 40 pages, and forms an excellent summary of the subject The section dealing with hydrogen-ion concentration is written so clearly that even the most elementary student could understand and take an interest in it In the chapter on enzymes it is instructive to see that doubt is thrown upon the value of the Abderhalden reaction The authors make their opinion quite clear by the fact that they give one reference to work in favour of Abderhalden's views, and eight references to work which contradicts his claims

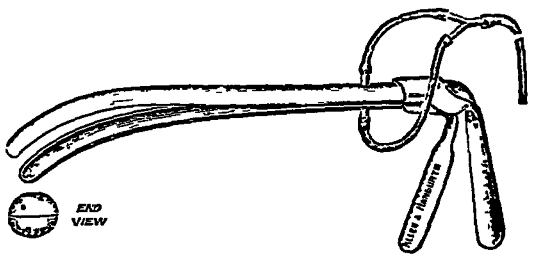
In the section on carbohydrates it is stated that "there is reason to believe that the normal organism converts ordinary glucose to the γ variety as a preliminary to oxidation, a power which is lacking in diabetics" This should have been supplemented by reference to the various criticisms of this view The chapter on the constitution of proteins is disappointing in that no account of the modern work on methods of protein analysis is included The synthesis of peptides is dismissed with a word, and no reference is given to the work of the modern German school on the diketo piperazine structure of proteins The chemistry of gastric digestion together with methods of gastric analysis, is dealt with in a most thorough and excellent manner No mention is made of the methods of preparation of the bile pigments, which are very easily obtained from gall-stones, and this is regrettable, because their preparation forms a very useful exercise for students The properties of hæmoglobin and its disintegration products are discussed rather superficially For instance, on page 339 in a schematic representation of hæmoglobin and its derivatives and how they are obtained, hæmatin does not appear in the scheme, although acid-hæmatin and alkaline-hæmatin are shown as being obtained by the action of dilute acids and alkalis respectively on oxyhæmoglobin The student might form the erroneous idea that hæmatin can be obtained by neutralising one or other of these solutions The relationship between these bodies and the classical hæmatin as described by Hoppe-Seyler and by Gamgee is not made clear In the section on blood analysis on page 371 the usual Folin method for the determination of blood-urea by distillation is given, though experienced workers know that it is impracticable owing to the excessive frothing which takes place The authors do not mention the methods of surmounting this troublesome complication The new chapter on the endocrine organs is a very up-to-date summary of this interesting subject, and is well adapted to the needs of students The remainder of the book maintains a high standard. Its only possible disadvantage for general use is its high price, but it must be remembered that the volume is a very large one, comprising nearly 1000 pages, and contains complete details for practical work on almost every branch of biochemistry

The work is one of the most comprehensive and practical to be found in any language It is well produced and such criticisms as we have made are noted only because further editions will certainly be called for

New Inventions.

UTERINE DOUCHE DILATOR

The illustration shows a new uterine douche dilator made in two halves, which, when closed, resemble an ordinary uterine douche Each half is hollow and is perforated at the distal extremity, so that fluid can pass through it and be sprayed out at the end The douche is passed into the uterus in the usual manner, and then by slight pressure on the handle it is made to open By this means the cervix is held open during the process of douching, thereby facilitating the passage out of the uterus of any foreign matter



Messrs Allen and Hanburys, of Wigmore-street, London, are the manufacturers

British Institute of Philosophical Studies — A meeting of this Institute is to be held on Feb 15th, at which Prof Julian Huxley and Mr Morris Ginsberg D Litt, are to speak on the Claims of Eugenics Sir William Beveridge will occupy the chair As usual a certain number of seats will be reserved for the general public and can be obtained on application to the Director of Studies at the above address

THE LANCET.

LONDON: SATURDAY, FEBRUARY 12, 1927

DOCTOR AND REGISTRAR.

AT bottom it is the practitioner who is the vital statistician. From his verdict as to the fact and cause of death there is no appeal; the rest is commentary or deduction—deduction, it is true, of a high numerical order but depending for its value on the practitioner's death certificate. The practitioner certifies both the fact and the cause of death. The former task is not yet laid upon him as a legal duty, but public feeling has been growing from year to year that the safety of the community is best served by making the medical profession responsible for the fact of death. Until the autumn of 1924 the formal certificate allowed him to insert the words "as I am informed," if he did not feel justified in taking upon himself the responsibility of certifying the fact of death. The new form, Y, requires him to state plainly that he has seen, or has not seen, the deceased since death, and in the new regulation which came into force with the present year[1] the local registrar is instructed to report to the coroner any death where the contents of the medical certificate show that the deceased was not seen after death by the certifying practitioner, and was not seen alive by him within 14 days of the date of death. To this extent and of course in every case where violence has occurred, the coroner assumes responsibility, but in regard to the cause of death the practitioner's field is now undisputed. In the seventeenth century it was customary in London to swear in ancient matrons who examined "by what disease or casualty the corpse died," making their report to the parish clerk on the Tuesday in each week. More than 80 years ago, at the instigation of WILLIAM FARR, the Royal Colleges and the Apothecaries invited practitioners generally to give in every instance an authentic name to the fatal disease under their care, preferably its popular or common name, with a statement not exceeding ten words in length; and in 1845 the Registrar-General began to supply practitioners with books of blank certificates asking them to distinguish between primary and secondary causes of death. A joint committee appointed by the College of Physicians of London came to the aid of practitioners in filling up these certificates and in 1869 issued a Nomenclature of Diseases suitable to England and to all countries where the English language is in common use with the further object of laying the foundations for a nomenclature in any language extant on earth. The former aim has been realised and the Nomenclature has appeared since at ten-yearly intervals, the current edition[2] being dated 1918, and the sixth edition being due in 1928. Their ambition to found an international nomenclature was not realised; in the early editions equivalent terms were given in Latin, French, German, and Italian, but these gradually dropped out, Italian being the first to go, and the present Nomenclature is solely in the English language. The preface expresses the hope that all medical practitioners will use the book for the return of causes of death, uniformity of terms being of the greatest importance for all statistical purposes.

Even with the aid of the R.C.P. Nomenclature the task of the certifying doctor is none too easy. The size of the 1918 edition is sufficient evidence of this; the list of diseases occupies 250 pages, and the index contains some 6300 entries. Set this against the London Bills of Mortality in 1668, when 75 headings included all possible diseases and casualties,[3] ten consecutive entries taken at random being king's evil, leprosy, lethargy, livergrown, lunatick, megrims, measles, mother, murdered, overlaid. A number of the more general terms in the present day list may seem as vague as these to a later generation, and there is certainly scope enough for choice without the use of the indefinite or undesirable terms of which the Registrar-General has drawn up a list for the guidance of practitioners. A selection from this list is given on a later page of this issue. Ten years is a long interval for revision of terminology in a live profession; terms are continually dropping out of medical use and new terms as continually gain the sanction of usage or convenience. Dr. PARKES WEBER called attention last week to some examples of this tendency and no doubt the joint committee of the Colleges will consider this and other suggestions at the forthcoming decennial revision. But even when no difficulty of nomenclature arises there are many pitfalls in the use of the partitions in the certificate. What is the primary, secondary, or terminal cause, in spite of the logical definition given on the certificate, must often remain a question of opinion. The consumptive who is attacked with influenza and ends his own life during the period of resulting depression, the diabetic woman who gives birth to a child and dies with a pulmonary embolism, are only two examples of familiar perplexities. And although the practitioner is not asked to anticipate the problems of tabulating causes of death, he is asked to bear in mind certain principles, as the inclusion under violence of all deaths from unnatural causes, including anæsthetics and poisons of all forms, the mention of childbirth wherever this has been in any way a contributory cause of death, attention to the seat of the primary lesion in cancer, and to the vaccinal state in a death from small-pox. With regard to diagnostic difficulties it cannot be too widely known that the Registrar-General welcomes information from practitioners as to causes of death not available when the certificate was issued, especially where a post-mortem examination or bacteriological investigation has thrown light on the precise cause.

The work of the Registrar-General may not be easy technically but it is simplified in this country by the fact that he does not undertake to tabulate the causes of death but simply what the practitioners say are the causes of death. It is not his business to revise a diagnosis even if he may be sure that it is wrong. To take an example some hundreds of deaths yearly are certified as being due to status lymphaticus or status thymicus, in spite of the almost conclusive demonstration by Prof. J. A. HAMMAR of Uppsala, that the criterion—namely, enlargement of the thymus—on which this diagnosis is based, is without value, but so long as practitioners certify lymphatism, the Registrar-General must tabulate in his list the deaths assigned to it. Similarly, food infections will still be entered up as ptomaine poisoning if the practitioner retains his faith in its existence. For his annual report the Registrar-General works on the primary causes of death as returned by the certifying practitioner, although the number of possible fatal diseases is so great that separate returns for each would be impossible. He therefore arranges the majority of these in groups of more or less related causes under single headings, and in the Manual,[4] which is summarised on page 359, reasons are given for the composition of these groups, of which there are at present 205 forming what is called the "Short List." The International Commission of 1920 gave its assent to the slight variants in this list rendered desirable by the particular circumstances of the British Isles, along with numerous deductions, eight headings of obvious value have been added—namely, encephalitis lethargica, meningococcal meningitis, rheumatic fever, diabetes, arterio-sclerosis, pneumonia, ulcer of the stomach and duodenum, bronchitis. The Registrar-General's next problem is to select for tabulation one out of a number of causes of death where more than one is given in the practitioner's certificate. The general order of preference has been chosen with a view of serving the interests of justice and public health. Violence takes precedence of every other cause, as the safety of the subject stands first. Epidemic disease takes precedence of local disease, in order that the risks to public health may be correctly assessed. The examples of selection given on a later page make good reading for the practitioner inasmuch as many of them are concerned with the dark corners of practice. Usage differs somewhat in English and Scottish head offices but the aim is the same in both. What exactly are the principles which should guide this precedence will be again discussed at the forthcoming revision of the International List by the Health Section of the League of Nations at Geneva, when the Section will have before it the suggestions of a British advisory committee of clinical experts, on which the College of Physicians has just appointed Dr. Robert Hutchison as its representative. Finally, the General Register Office goes over the same material again at ten-yearly intervals to show the local distribution of certain causes of death. The great image built up on the practitioner's death certificate is certainly imposing, those who throw stones can only do so with any hope of success if its feet, as in Nebuchadnezzar's dream, are partly of clay.

EPIDEMIC POLIOMYELITIS

THE epidemic of "infantile paralysis" which occurred last autumn attracted more public attention than any previous outbreak of this disease. The chief reason was that the affected communities included a famous public school and the Military Academy at Woolwich, and owing to heated argument the main issues became confused out of recognition. The sober discussions promoted on Friday last by the Association of Medical Officers of Schools (p. 321 of this issue), and on Monday by the Medical Society of London (p. 340 of this issue), have done the great service of resolving much of this confusion and of collating the knowledge, not perfect but nevertheless considerable, possessed by those in this country who have given the subject their closest study. In Dr. James Collier's words, addressing the school medical officers, "the public health aspect of poliomyelitis bristles with difficulties and dangers, ignorances and paradoxes," and, so far from being disputed hotly in the daily papers, should be approached with extreme caution and in a spirit of constructive reverence exclusively by those whose experience gives them the right to undertake such a grave responsibility. The ultimate problems of the disease will be solved only by "careful clinical observation, which cannot lead us astray," and by the united efforts of general practitioners, any of whom may find out the importance of some hitherto unobserved fact.

It is practically established that the malady is communicated by human contact only, the medium of infection being the secretions from the upper respiratory membranes and the portal of entry the nasopharynx. Incidence is greatest in the late summer, and most of the victims are between two and five years of age. Incubation usually takes three or four days, but may require twelve in some patients or be complete after two in others. The infection seems to be spread almost entirely by carriers, who are generally people in whom the course of the disease has been abortive. Dr. Collier does not believe in case-to-case infection, and his experience of carriers is that their virulence is at its highest at the onset of the disease and wanes in a few days. The carrier does not often die, and the "chronic healthy" carrier of typhoid has fortunately no counterpart in poliomyelitis. Notwithstanding the events of last autumn, he holds it to be a fact that the disease does not like schools, institutions, and large towns, the reason being probably that the resistance of the population in these places is high. As Dr. F. Walshe said, in opening the discussion on poliomyelitis before the Medical Society of London, "either most infants suffer from an abortive form of the disease in early life and thus acquire permanent immunity, or there is a particular and limited class of persons whose healthy nasopharyngeal secretions lack the necessary protective bodies," but whichever speculation be true, poliomyelitis certainly will not vegetate like measles, small-pox, and varicella, on every soil. The community that has most to fear from it is the small, comparatively isolated group, which has never been "salted." Dr. Collier contrasts two types of epidemic, one in an "unsalted" West country village, where 45 people out of 119 contracted poliomyelitis within a few days of the arrival of a carrier, and the other in Edinburgh, a highly salted community with multitudinous carriers. The latter epidemic was limited to 62 cases of the usual spinal type. Contact was absolutely excluded in all but three patients, and only six suffered from headache. Both the authorities we have quoted agree on the importance (to any study of the epidemiology of poliomyelitis) of the work of W. W. Topley and Major Greenwood on animal communities and of Surg.-Comdr. S. F. Dudley on certain semi-isolated human communities. Topley and Greenwood found that the spread of an infection in an isolated community of mice was limited by dividing the herd into small groups and segregating them from one another. This soon got rid of the infection, but if fresh susceptibles were admitted to the herd the virulence was increased. Even when an epidemic seemed to have died down the new susceptibles acted as fresh fuel resuscitating it so that in the end even the immunised members succumbed It is much safer, in fact to introduce a thousand susceptibles to an infected community all on the same day than 10 a day for 100 days Comdr Dudley remarked that the morbidity from infections was four times greater in Greenwich Naval School than in the London elementary schools, yet the boys in the naval school are the pick of the board schools The reason for this, he says is that droplet infections are spread essentially in the dormitory not in the playground or class-room the rate of spread varies inversely as the distance between individuals In a mixed boarding- and day-school it is the boarders who suffer

[4] Manual of the International List of Causes of Death as Adapted for Use in England and Wales, Scotland, and Northern Ireland. Based on the third decennial revision by the International Commission, Paris, 1920. H.M. Stationery Office. 1926. 2s.

The autumn outbreaks excited a vigorous controversy between those who held that a boarding-school attacked by poliomyelitis should be enclosed and quarantined and those who advocated dispersal the embarrassing feature of the dispute being the assumption by either side that one policy only could be right and that the other must necessarily be wrong It must, however, be remembered that this position was inevitable, for advice had to be given promptly in an emergency, the two policies could not run concurrently, the advisers could not give counsel which would cover two diverging procedures Dr Walshe sums the question up very fairly by suggesting that to take the view that the correctness of one course is the condemnation of the other in our present very incomplete state of knowledge, ' is to place a very complex situation upon the Procrustean bed of an unjustified generalisation There are obvious objections to either policy, and it may be doubted whether either has a universal validity " Assuming that a headmaster will, as it is only reasonable to expect, consider the safety of his pupils first and the community at large second, then the choice between isolation and dispersal must, Dr Walshe says depend entirely upon the local conditions The latest research work shows that the measures for stamping out infection in a boarding-school must include the segregation of the pupils into small groups of which each must be isolated from every other group, the spacing of beds at such a distance that infection by droplets is impossible, and the exclusion of fresh susceptibles until a long time after the epidemic has died out If local conditions do not permit these steps to be taken and rigorously enforced —and the number of schools in which they are practicable may be small—then the policy of isolation and quarantine is not justifiable on its merits The possible consequences of the disease include severe and permanent disablement, and each fresh case increases the period of isolation and the chances of contact infection The objections to the opposite policy of dispersal are also very great. for it is known that the disease is spread perhaps entirely, by carriers, and the probability of some of the released contacts infecting the district in which they live is a formidable one The risk will increase inversely as the effectiveness of the segregation measures taken by the parents at home We must agree with Dr Walshe that although closure is the method of choice when it can be properly carried out under ideal conditions these conditions are not always present Where the responsibility is assumed of breaking up a school every possible step must be taken to enlist the coöperation of the parents in the interests of the public safety As a matter of fact the schools show great tendency to break themselves up for no pupil unless he can be regarded medically as unfit to travel either on his own account or on public grounds can be detained in defiance of parental instructions

ATMOSPHERIC POLLUTION· A YEAR'S RECORD

The Advisory Committee on Atmospheric Pollution has just published its twelfth annual report[1] covering the year ended March 31st 1926 The first section summarises the returns from 29 authorities having 61 deposit gauges and shows the monthly deposit divided into rainfall insoluble and soluble matter The insoluble matter is further subdivided into tar, carbonaceous matter other than tar, and ash. the soluble matter into loss on ignition and ash Further partial analysis of the soluble part is made into sulphates, chlorine and ammonia The highest tar deposit was found at Burnley: the lowest at Bournville, Southport (Hesketh Park), and Leeds (Headingley) The highest deposit of carbonaceous matter (soot) was at Newcastle-on-Tyne (City Road). the lowest at Rothamsted The highest deposit of sulphates was at Wakefield, the lowest at Leeds (Headingley) In most of the stations there was a slight reduction in the amount of impurity deposited when compared with the average of the previous five years the total deposit in 36 stations being below the average in 24 and above it in 12 The deposit of tar was higher in the winter than the summer at 28 of 45 stations The insoluble ash, with which would naturally be included wind-blown dust, was higher in the summer than the winter at 32 of 46 stations The winter deposit of chlorine was higher in 41 of 45 stations a fact probably connected with the stormy weather in winter which raises spray from the surface of the sea The automatic recorders installed at Blackburn and Stoke-on-Trent show that these cities differ from other cities in the distribution of their atmospheric impurities, in the latter case the curiously irregular curves are doubtless due to the periodic emission of smoke from the pottery ovens An attempt has been made to bring out a weekly time-table of the smoke-haze in certain localities; in Westminster there is a falling-off after Thursday, at South Kensington the haze is scattered fairly evenly over the week while at Kew the maximum is towards the end of the week Dust counter observations are dealt with in the third section of the report where the method of obtaining samples of the soluble crystalline matter in the dust is illustrated, with reference to Dr J S Owens's demonstration before the Royal Society of the bearing of deliquescence of microscopic crystals on fog formation The United States Weather Bureau has recently confirmed the relation between visibility, relative humidity, and the number of dust particles as estimated by the Owens dust counter Illustrations are given of the curious spherical dust particles derived from furnace ash The fourth section of the report also deals with the obstruction of ultra-violet radiation by smoke and with the quantity of smoke impurity in the air the conclusion is reached that there is a distinct relation between the amount of radiation received on the ground as measured by Dr Leonard Hill's methylene-blue method and the amount of smoke pollution The observed relation of sulphur deposit to total deposit is interesting, when the total deposit is small the percentage of sulphur is high and vice versa For example. Leeds (Headingley) with a total deposit of 1531 metric tons per hundred square kilometres in the year shows a sulphur percentage of 23 6 while Newcastle-on-Tyne with a deposit of 21 580 for the same period shows a sulphur percentage of 7 1 An attempt to measure the deposit hour by hour is described by Dr J R ASHWORTH in an appendix

[1] Meteorological Office Air Ministry M O 290 H M Stationery Office 1926 6s 6d

The valuable work of the Advisory Committee is to continue, although it is not yet quite certain under what conditions We understand, however, that it has now been arranged for the work to be carried on under the Department of Scientific and Industrial Research, the new regime being established from April 1st next This should be a step in the right direction as it will bring into close relationship the work of the Committee with that of the Fuel Research Board The Committee has aimed simply at measuring the impurities in the air and collecting data on the degree and nature of pollution, whereas the investigation of methods of preventing smoke is a legitimate function of the Board During the last year there has been a definite increase in interest taken by the general public in the purification of the air, partly due, no doubt, to the growing conviction, now a matter of public knowledge, that sunshine, and more particularly ultra-violet radiation from the sun, are essential to health It is true that there are still many persons who do not wish to have industrial processes interfered with, however much they affect the health of others There is, however, before Parliament a Bill which aims at the reduction of the smoke nuisance What result will follow its enforcement it is hard to say, for as the domestic fire is not to be included in its purview we cannot hope for any reduction in domestic smoke as a direct result Indirect advantage may nevertheless arise from the encouragement to develop smokeless solid fuels such as low-temperature coke, or to improve the quality of ordinary high-temperature coke so as to make it a more satisfactory fuel for domestic use On the whole the prospect is brighter year by year as more people come to realise that all is not well when they are compelled to live in a soot-laden atmosphere

Annotations.

"Ne quid nimis"

PHYSICAL EDUCATION OF THE ADOLESCENT.

THE Report of the Consultative Committee of the Board of Education on the Education of the Adolescent[1] raises issues affecting not only the educational system, but also the general social and industrial organisation of the country The conclusion is reached, from a study of the history of the development of our elementary system of education and of its present features, that all children should be transferred at the age of 11 or 12 years from the "primary" school to schools of the present "secondary" or "central" types Both of these "post-primary" schools should give a humane and general education, but the former is designed as a stepping-stone to higher education, and the latter is to be related more closely to the living texture of industrial or commercial or rural life In other words, "post-primary" education should be adapted to foster such inherent capacities as may be possessed by the individual scholar In this wide survey physical training has not been omitted, but has scarcely received the scrutiny it deserves The Committee's conclusion that every modern school should have a playing field of its own, especially in large towns, and that in crowded areas, a play field should be provided for a group of several schools in a district, each having the right to the use of the ground on stated days, or at stated times, will be welcomed

But many will hardly agree with the statement that "Most games and sports, while contributing largely towards general health and fitness, tend to produce a rather ill-balanced development of the body and require to be supplemented by systematic physical exercises" Does any outdoor game tend to produce ill-balanced development that really requires corrective physical exercises? The relative merits of systematic exercises and group games have not been discussed and no indication has been given as to the type of instruction, nor as to the time that should be devoted to physical education, although reference is made to the Syllabus of Physical Training for Schools, 1919, issued by the Board of Education The Board intends shortly to publish a reference book of gymnastic training for boys' schools, other than elementary, which provides for continuously progressive training up to the age of 18 and a somewhat similar book for girls up to the age of 16, and probably it is for this reason that few details are given now But we feel that an opportunity has been missed by the Committee in their failure to show clearly the need for a uniform and comprehensive system of training In the "primary" schools, where the children have not yet progressed to the group game level, a graded system of exercises passing gradually into simple games and athletic activities is necessary and should be an integral part of the curriculum The way will thus be prepared for the advance of the adolescent, in whom the communal game instinct is fairly well established Provision must be made for a sufficiency of fully trained teachers to undertake the direction and supervision of physical training as a whole, and sufficient time should be allocated in the curriculum for such training, there must be suitable facilities and equipment for games and play, since both guidance and adequate playing opportunities are required to encourage and develop the self-reliance and restraint, loyalty and resourcefulness necessary for team-work

ENDEMIC GOITRE IN THE UNITED STATES

IT has long been hoped that the collection of exact information as to the distribution of endemic goitre in different parts of the world would aid in the determination of the cause or causes of enlargement of the thyroid gland Diligent search has been made for the special conditions which obtain in districts where goitre has been found to be prevalent Geological formation, fæcal contamination of the drinking water, and scarcity of iodine in the food and drink in the affected area have, each in turn, been held to be largely responsible for the occurrence of the malady A satisfactory solution of the problem, however, is still wanting Goitre is very prevalent in some of the United States, and in a recent report on the distribution of endemic goitre, published by Dr Robert Olesen[1] of the United States Public Health Service, the known facts with regard to its distribution have been brought together Much valuable information as to the frequency of the disease in men of military age was obtained from the records of the draft examinations during the war, although, as goitre is more frequent in women than in men the numbers obtained are smaller than those which would be got from a survey of all the inhabitants of each State The total number of men examined was 2 510,701, and the figures show a wide variation in different States To take a few examples the ratio per 1000 in Idaho was 26 91, in Oregon 26 31 in Illinois 7 79, in New York 1 19 in Maine 0 66 and in Florida 0 25 Generally speaking, the figures thus collected indicated a greater frequency of goitre in the Great Lakes Basin Pacific North-West and in the than elsewhere The results of a number of surveys made in different parts of the United States largely agree with those obtained by the examination of the drafted men. But these surveys are of relative value only, owing to the different views held as to what really constitutes a goitre. It is most important that a uniform method of examination and record should be adopted in all districts. and indeed in all countries and that some degree of abnormality should be decided on as a standard In America some resurveys have been made and with due precautions these should yield information of value in determining any change in the incidence of goitre which may have occurred as a result of the adoption of prophylactic measures in any given area If possible they should be made under the same supervisor, so that the personal factor remains constant

[1] Public Health Reports Distribution of Endemic Goitre in the United States as shown by Thyroid Surveys vol xli No 48.

So variable have been the reports from different places, that it remains difficult. for example. to decide whether the general administration of iodine to school-children in goitrous areas is desirable. In the Central States as in other parts of the world: this measure is said to give good results and it can hardly be thought unreasonable where its aim is merely to raise the intake of iodine to a normal level The results however, are conflicting and in any case it is unwise in this country to encourage the wholesale use of iodised preparations some of which certainly contain far more of the drug than the body normally requires In the wise words of Dr. Donald Guthrie,[2] of Pennsylvania, "the public should be warned of the great danger in the self-administration of iodine for the treatment of goitre and physicians should have a clear understanding of the types of goitre that are amenable to the iodine treatment and of the danger which attends its incorrect use" Instead of this we see articles in the lay press and notices in chemists shops instructing people to regard iodine as a general tonic and especially as a preventive or cure for goitre

ACTION OF PHENOL ON PROTEINS

POISONING by drinking phenolic disinfectants still occurs with sufficient frequency to render any study of the action of such bodies on the constituents of the animal of interest to the medical profession. In the current number of the *Journal of Physical Chemistry* E Ashley Cooper and E Sanders[3] describe work on the relations of phenol to proteins and other colloids Cooper and Woodhouse in 1923 had found that the uptake of phenol from aqueous solutions by proteins in its first stage followed the partition law—that is there was a consistent ratio between the concentration of phenol in the aqueous solution and the protein As the concentration of phenol was increased, the protein began to absorb greater (up to 12 times) proportions of phenol and to separate from solution. The present work has been carried out on the proteins of serum, on the muscle proteins myosinogen, and paramyosinogen, on the vegetable proteins edestin and gliadin, on gelatin treated in various ways, and on such inorganic colloids as ferric hydroxide hydrosol and silicic acid as well as on soap The authors point out that there is great similarity between the action of phenol, of alcohol and of heat; they remark that those bacteria which are most susceptible to the disinfection by alcohol and phenol are also most susceptible to the action of hot water. the action in all cases being apparently due to de-emulsification of the protein. Heat coagulation of proteins like that produced by phenol is known to occur in two stages—first denaturation then agglutination It appears that the second of these stages is associated with the greatly increased solvent power of the protein for phenol, denaturation having no effect on the partition of phenol between water and protein The increased absorption the authors are inclined to attribute to association of molecules of phenol This view is somewhat supported by the relative behaviour of phenol and the less toxic dihydric phenol resorcinol which although it coagulates gelatin is. unlike phenol not then absorbed by it to any great extent Phenol forms associated molecules in some solvents—e.g. benzol—whereas resorcinol does not. The inorganic colloids had no absorptive power for phenol but soap, although not coagulated, showed two stages of absorption The denaturation of albumin by various means including electrolysis, has recently been studied by H Mastin and C B. Schryver,[4] who find that a well-defined acidic product is formed containing an increased number of acid groups, but not of basic groups. and bring forward evidence for a new type of linkage of carbon and sulphur in proteins The former work was done at the University of Birmingham the latter in connexion with the work of the Adhesives Committee of the Department of Scientific and Industrial Research Both researches have an important bearing on those irreversible changes induced by phenols or by electric shock. which are associated with death

CANCER IN THE FIELD

THE ætiology of cancer can be approached in many ways At one end of the scale we have Dr W E Gye's intensive investigations in the laboratory, at the other end Dr L W Sambon s expeditions in search of significant relations between incidence and environment. The general idea behind Dr. Sambon's work evidently is that cancer is caused by a parasite. or by something like a parasite, and that this agent comes from. or has some relation to some animal or plant Observations along these lines appear in the third report of the Cancer Field Commission[5] which works under his direction. with the support of the Tropical Disease Prevention Association and with financial aid from the British Empire Cancer Campaign. This report describes researches on the epidemiology of cancer made during 1925 in Italy and Holland and deals incidentally with so extraordinary a diversity of topics that it is possible to summarise only a few of them. Cancer distribution and cancer prevalence says Dr. Sambon, vary from place to place, irrespective of climate. race food. type of dwelling, habits and customs. As a rule cases of cancer are distributed in groups or clusters; a first case is usually followed by one. two three, or more cases, either in the same house or in adjoining or neighbouring houses Frequently in a cancer cluster the patients are affected in the same organ which suggests a common source of infection. The evidence in favour of these statements consists of maps and case-lists vouched for by local physicians and by civil and ecclesiastical authorities but the propositions are so fundamental that they can hardly be accepted without more information than Dr Sambon offers: the questions which they would answer are among the most difficult in statistical epidemiology Following the assumption that cancer is indeed a disease of places Dr. Sambon naturally proceeded to investigate the fauna and flora of implicated localities. Considerable attention was paid to worms for. like many others he interprets Fibiger s production of cancer by irritating rats stomachs with the worm *Gongylonema neoplasticum* as evidence that the worm either carries a parasite which causes cancer or sets up a condition which favours the entrance of such a parasite. A number of interesting observations were made of the occurrence of species of *Gongylonema* in men pigs cattle. and rats and in their intermediate hosts (cockroaches and beetles) and Dr. C Bonne describes in detail a wild rat caught in Italy which had an epithelial tumour of the cardiac end of the stomach associated with the worm *Hepaticola gastrica*—a coincidence which has been seen three times before The known examples of worm-infection preceding cancer in men and animals are reviewed and Dr Sambon rightly points out that, whatever the details of the association may be, it is no doubt possible to control the prevalence of worms by hygienic methods and so, to a greater or less degree control the prevalence of cancer. Tumours in plants (crown-gall, ordinary galls, &c) are also noticed with the idea that animal cancers may have the same origin. In all that relates to worms, the Commission has had the expert help of Dr H A Baylis. Mr J Ramsbottom similarly contributes notes on the fungi found in cancer-houses and on other matters which fall within his province. Entomology is dealt with by Mr K G Blair, who investigated the insect hosts of *Gongylonema*, and the fauna of suspected houses and drinking fountains. Finally, Sir Lenthal Cheatle gives some histological notes on the tumours which were obtained. All these writers have something of interest to contribute, how far their facts really have to do with cancer time alone will show. It may turn out, after all, that cancer is due to an extraneous virus, and Dr Sambon may be following a fruitful line in examining all the avenues by which this virus may be implanted in the body. In any case the Field Commission is pursuing a refreshingly independent course, in attempting to solve problems which ramify so widely.

CARCINOMA OF THE SMALL INTESTINE

Dr Edmund M Clark, of Indianapolis, who reports a case of colloid carcinoma of the ileum,[1] quotes some interesting statistics to illustrate the rarity of carcinoma of the small intestine. Of 466 cases of intestinal cancer found at the Vienna Pathological Institute during the period 1870-93 only 25 were located in the small intestine, 13 being in the duodenum and 12 in the ileum. A review of the recorded cases shows that primary carcinoma is commoner in the duodenum than in the jejunum or ileum, and that the jejunum is least often the site of malignant growths. According to Ewing tumours of the small intestine occur in three distinct forms (1) As part of a general or local polyposis (2) As multiple or single embryonal carcinoid tumours which are usually found in the ileum or jejunum as single or multiple firm opaque nodules in the mucosa or submucosa, differing in structure according as they arise from pancreatic island tissue, heterotopic intestinal mucosa, or glands (3) As localised adenocarcinomata arising from single intestinal polypi. Most intestinal carcinomata are of the last type. The average age of patients with carcinoma of the small intestine is 46½ years, though a case has been reported in a child aged 3½ years. About 70 per cent of all cases of carcinoma of the duodenum are localised in the ampulla. In the jejunum and ileum carcinoma occurs either as a degenerative polyp or as a ring cancer like that seen in the large intestine. The symptoms at first are indefinite, being loss of weight, asthenia, and vague abdominal discomfort. In the cases reported in the literature an early diagnosis was not made. In the later stage signs of intestinal obstruction develop. The symptoms of the greatest diagnostic value are stubborn constipation—with or without alternating diarrhœa—severe attacks of colicky pain, and vomiting. With the increasing obstruction visible peristalsis and a palpable tumour may be found. Gross blood is rarely present in the stools, but occult blood may be detected and is a useful guide to diagnosis. Radiography is also of great assistance and serves to localise the lesion, as was shown in Dr Clark's case, with fair accuracy. The prognosis is gloomy, but is most favourable when the growth is situated in the jejunum. Treatment is, of course, surgical lateral anastomosis being required if removal of the tumour is impossible. In Dr Clark's case, which occurred in a man aged 59, the pre-operative diagnosis was intestinal obstruction. The patient had suffered from indigestion for many years but there was a definite increase in the intensity of the gastric symptoms about six months before the onset of intestinal obstruction. At operation the tumour was found in the ileum about 12 inches from the ileocæcal valve. About 8 inches of bowel were resected and a side-to-side anastomosis was made. Recovery was uneventful.' The growth proved to be a colloid carcinoma which is the rarest type of carcinoma found in the small intestine. In connexion with obstruction in the small intestine it should not be forgotten that a nodular constriction of the gut may possibly be secondary to cancer of some other organ as was illustrated by a case recently published by Mr Alan Perry in THE LANCET (Jan 29th, p 226). A second case was described by Mr Perry in which a ring-like stricture of the jejunum proved to be syphilitic.

HYPNOTISM AND ANÆSTHESIA

THE relationship between hypnosis and anæsthesia is a close one, whether viewed historically or from the point of view of the physiologist. Historically it may be recalled that the use of hypnotism for allowing painless performance of surgical operations was at its height shortly before the introduction of nitrous oxide, ether, and chloroform. And it is probable that the work of Esdaile on hypnosis would have been followed and extended by other surgeons had it not been for the advent of these far better aids to surgery, the general anæsthetics. The physiological relationship of the two states, hypnosis and anæsthesia, was explained by Dr S R Wilson in the paper he read before the Section of Anæsthetics at the Royal Society of Medicine on Feb 4th. Both of the states mentioned depend on inhibition of the volitional cortical layer of cells and consequent freedom of the lower layers. Dr Wilson expounded the modern view of reflex action as founded by the work of Sherrington and of Pavlov, and showed how these views provide a sane and scientific hypothesis for the explanation of the phenomena of hypnosis and suggestion, which are now, of course, completely removed in the minds of the instructed, from that suspicion of delusion or "thought-reading" or "spiritualism" with which they were formerly wont to be regarded. Dr Wilson further showed how justly and with what great advantage suggestion may be employed for the patient's benefit if it is introduced by the anæsthetist at the correct stage of early narcosis—viz, at that time, when, although volition is abolished, senses and reflexes are active and impressionable, and memory can be firmly stamped. Dr Wilson illustrated his theories by one or two simple, striking, and completely successful demonstrations.

FOCAL NEPHRITIS

IN the investigation of the diseases of any organ it frequently happens that one of the first results is the separation of some group of cases which can be given a satisfactory pathology and which form a starting-point for fresh classification. This has been well illustrated in the recent separation of coronary thrombosis from the heterogeneous mass of clinical and pathological material grouped under the heading of angina pectoris. And now acute inflammation of the kidney is being gradually classified into several subdivisions, and focal or embolic nephritis is one of the first of these smaller groups to be described. This form of acute nephritis occurs practically only in the course of infective endocarditis, and is a condition of multiple infarction of the kidney by emboli of infected material derived from the cardiac valves. Another group of cases of acute nephritis has been separated off within recent years under the heading of acute hæmorrhagic nephritis, described, as it occurred in 22 children, by W G Wyllie and A Moncrieff in these columns.[1] Since this account numerous cases of the condition have been reported under the title of acute hæmorrhagic nephritis and a recent paper by W S C Copeman contains the records of four typical examples.[2] It is important to remember, however, that this form of acute nephritis is closely allied to embolic nephritis in its pathogenesis. According to the description given by Wyllie and

[1] THE LANCET 1926 i, 128

[2] West London Med Jour 1926, xxxi, 225

Moncrieff, in acute hæmorrhagic nephritis "blood appears in the urine quite suddenly, sometimes during, but usually a few days after some acute or subacute infection of the nasopharyngeal region, and may continue to be passed in smaller quantities for several days or weeks" Thus, these authors thought, was due to "multiple emboli of streptococcal origin without any widespread inflammation of the kidney substance" As a matter of fact this condition had already been separated from acute nephritis by Volhard and Fahr, who offered the same explanation, and a good account of it is given in Dr Herman Elwyn's recent work on nephritis under the heading of 'non-embolic focal glomerulo-nephritis" Dr Elwyn is a New York physician, and his description of the condition is very similar to the account of it as it occurred in the 22 children referred to above, and he emphasises the importance of eliminating all possible sources of infection in cases of recurring focal nephritis He thinks that this form is perhaps "the most common form of nephritis," and it would seem better, in view of the increasing difficulty in securing uniformity in the classification of diseases of the kidney to classify acute nephritis as diffuse or focal, and to divide the latter group into embolic and non-embolic, limiting the term embolism to the gross infarction occurring in infective endocarditis The term acute hæmorrhagic nephritis is thus avoided, which is probably advisable, since it may rightly be pointed out that all acute nephritis is hæmorrhagic, and the name does not give the clue to the essential features of the disease as the term "focal" certainly does.

DR. LEONARD HILL'S PICTURES.

AN exhibition open until Feb 25th, at the Alpine Club, Savile Row, of paintings by Dr. Leonard Hill will repay a visit; it shows that Dr Hill has definitely joined the small band of medical men, like Prof. Tonks and the late Sir Francis Seymour Haden for example, who have found in a medical training a sound introduction to artistic performance Of Leonard Hill of the National Institute of Medical Research his colleagues know a great deal, and some of them are also aware that he has practised painting as a recreation for many years, and has previously exhibited some of his work But no so large and varied a collection of his paintings has, we think, yet invited public attention There are upwards of 120 works in the Alpine Club Gallery, composed of a few pastels, and 36 water colours, the rest being in oil While the works, whatever the medium, vary from elaborate pictures to what may be regarded as interesting notes in colour, whether they be large or small, and whether solid or elegant, they have in common the properties of luminous colour and high regard for spatial perspective Large, almost architectural, skies are made to reach over the landscape and to recede from the eye, and even in many of the smallest pictures the effect of a considerable range of scene is obtained by scrupulous regard for values And it is only here that Dr Hill has any scruples—i e, allows any discipline to control his work, for most of it has the unrestrained vigour born of that convinced intention and prompt execution which cannot be tied by regulation Many of the effects are obtained by an easy mastery of water or oil that is hardly expected from a painter who has gone through no intensive training at the student age For examples of these qualities the following pictures may be instanced First, in oil we should notice "The Harvest Field" (4) "The Poultry Yard in Snow" (2)—all kinds of poultry and especially turkeys have a great fascination for Dr Hill—"A Summer Pasture" (21), "The Hen Run" (22)—a delightful little scene "A Pastoral" (51), and "A Sandy Shore" (69), while the pictures numbered 33, 35 and 37 are good examples of the painter's objective and technique It is probable that among the water-colours more popular favour will be obtained, but there is no concession made here by Dr Hill to those who want merely pretty things The water colours are as strong and as sincere as the oils and several of them have high emotional value "Light on Cloud and Sea" (4), is a quiet and mysteriously luminous picture; "Sunrise Colours the Shore" (5), is gorgeous and happy: "The Rainbow over the Sea" (26), and the "Swede Heap" (27)—pictures at the extreme ends of Dr Hill's range of work—show his familiarity with atmospheric effects, and four Alpine Studies render faithfully the peculiar brilliancy of the snow scenes Dr Hill is to be congratulated upon his exhibition

STANDARDISATION OF ULTRA-VIOLET RADIATION

A CHEMICAL method for the standardisation of ultra-violet light is described in detail by J E Moss and A. W Knapp in the *British Journal of Actinotherapy* for January. It is to be known as the Uroxameter method, the name being apparently coined from two of the substances forming the chemical solution acted upon by the rays This solution consists of 20 c cm of a 2 per cent solution of oxalic acid, 5 c cm of a 1 per cent solution of uranium acetate, and 20 c cm of distilled water It is put in a circular flat-bottomed vessel which is 16 cm in diameter, and has vertical glass walls, 8 c cm high, and these walls are painted on the outside with one coat of red paint and three coats of white, so that the interior of the vessel appears red and the passage of light through the sides is prevented, while the white paint serves to reflect heat from the outside On top of the cell can be fixed a gas-tight lid of fused transparent silica The vessel containing the solution is placed 6½ inches below the centre of the lamp to be tested, and is rotated by means of a table at 5–6 revolutions per minute. Part of the test solution is titrated with a decinormal solution of potassium permanganate, in order to find the amount of oxalic acid which it contains Of the remainder, 45 c cm is then exposed to the light for 30 minutes and afterwards again titrated The percentage of oxalic acid which has been decomposed can then be ascertained, and this is proportional to the amount of radiation absorbed A large number of estimations have been made by this method to determine such diverse values as the variation in radiating power of mercury lamps, the colour-destroying power of the radiations, and the transparency of various glasses From spectrometer determinations it is clear that this solution strongly absorbs radiations shorter than 3200 A°V, and is therefore an appropriate medium where effects are due to rays in this region of the spectrum. The tests suggest that the method can be relied on for quantitative purposes, and we can well imagine that it would probably prove economical and suitable for industrial work It is not one, however which is likely to be adaptable to medical requirements Here as in the field of X rays, the first essential of any device for measurement, either of the intensity or of the total dose of radiation, is that it should be easy to use it at the same time as when the rays are actually being employed in treatment

THE FUTURE OF THE FOUNDLING HOSPITAL ESTATE.

THE signatures of a complete list of the medical men and women residing on the Foundling Hospital estate are appended to the following letter which has been addressed by them to Mr Neville Chamberlain, the Minister of Health.—

We, the undersigned medical men and women residing on the Foundling Hospital Estate, view with grave concern the growing tendency to build over the open spaces in the centre of London Endsleigh Gardens and Mornington Crescent have already been sold for building purposes and a Bill is to be introduced in Parliament in the ensuing session, with the object of obtaining power to erect a market on the grounds of the Foundling Hospital and the adjoining squares This site is largely surrounded by thickly populated areas and in its immediate vicinity are no less than seven important hospitals. Any diminution of the open spaces in this neighbourhood is bound to have an adverse effect on the health of the community

Open spaces, by acting as natural ventilators of the surrounding streets, diminish the incidence of infectious disease In London they have undoubtedly exercised a considerable influence in producing a low death-rate and a general high standard of health In this connexion it is worthy of note that the children of Foundling Hospital have been, over many years, extraordinarily free from tuberculosis, no definite case having occurred during the past decade

We would respectfully urge your consideration of the matter, and venture to suggest that the permanent preservation of the squares of the Foundling Hospital Estate would be a measure in the best interests of public health, and one which we earnestly hope may receive the sympathetic consideration of the Government

The letter is signed by —

C T Bishop, M B , J Christie-Anderson, M B Ch B , L D S , D Constantin, M R C S , L R C P , M Dia, M B , B S , D P H , Wm M Fairlie, M D , D P H , James Harold, L R C P I and S I , A O'Dwyer Kennedy, B A , M R C S , D A D Kennedy, M C , M B , Ch B , James Kerr, M A , M D , D P H , Edward Knight, M R C S , W B Knobel, M D , M R C P , Wm Macleod, M B , E Miller, M A., M R C S , D P H , C J O'Brien, M B , J J O'Donnell, L R C P I , Olive Rendel, M D , M R C P Maude M Richards, M B , B S , J V Rees Roberts, M D , D Sc , Eleanor C Thistlethwaite M B , Ch B , A F Whyte, M B , Ch B , G C Nelson Younger, M R C S

We trust that the views of these representative signatories will receive close attention before the future of the Foundling Hospital estate is definitely settled The value of preserving all possible open spaces in the more densely populated regions of the metropolis requires no argument, while other factors might have been introduced into a petition for the favourable notice of the Minister of Health The architectural features of the building are a heritage from the eighteenth century which should not lightly be dissipated, while this particular area of London has been lately regaining its residential character, and for many years has been meeting the needs of large and important sections of society whose interests are as worth considering from the public point of view as any commercial amenities We can conceive that with the gradual reconstruction of some of the larger houses into flats, alongside with the preservation of the beautiful gardens of the Foundling Hospital, a residential quarter already planned in bulk might develop into a real source of benefit as well as æsthetic delight

Mr. Neville Chamberlain, Minister of Health, has promised to unveil a memorial tablet to the late Sir Patrick Manson in the Manson Ward of the Royal Albert Docks Hospital, where he laid the foundations of the teaching of tropical medicine in this country, and where he carried on much of his research The ceremony will take place on Tuesday, March 15th, at 3 30 P M , and a train which leaves Fenchurch-street Station at 2 20 and arrives at Connaught-road at 2 41 P M will be found convenient It is announced that Messrs Cassell and Co will publish "The Life and Work of Sir Patrick Manson" on March 10th.

Messrs Martin Hopkinson and Co , announce the publication of a volume entitled "Medical Views on Birth Control" Edited by The Rev Sir James Marchant, it contains an introduction by Sir Thomas Horder and contributions from Dr H Crichton-Miller, Dr Leonard Hill, F R S , Dame Mary Scharlieb, Dr A E Giles, Dr R C Buist, Dr Letitia Fairfield, Sir Arthur Newsholme and Sir John Robertson

SCIENTIFIC CINEMATOGRAPHY —The Confédération Internationale des Etudiants has founded a Scientific Cinematograph Commission, consisting of representatives from student organisations in all countries, for the purpose of preparing an international catalogue of scientific films To awaken interest in this country in scientific cinematography the National Union of Students of England and Wales has organised an exhibition of scientific films at its third annual congress to be held at Bristol from March 24th to April 1st There will be a special exhibition of medical films, probably showing radiography and trepanning Full particulars may be had from the Congress Secretary, the National Union of Students, 3, Endsleigh-street, London, W C 1

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCX —TREATMENT OF ACUTE RETROPHARYNGEAL ABSCESS

THIS article will be restricted to a consideration of the acute form of abscess which occurs behind the pharynx, most commonly in children under 3 years of age No attempt will be made to discuss the rarer variety of retropharyngeal abscess, where the disease originates in the cervical vertebræ and remains behind the prevertebral layer of the deep cervical fascia This latter form of the disease is to be recognised by the greater chronicity of its symptoms, and by signs which point to a lesion in the vertebral column It is important to realise that the chronic abscess (usually tuberculous) is best approached by an incision in the neck, and in this respect differs from the acute and commoner form

Ætiology.

Acute retropharyngeal abscess arises either by direct spread backwards from an inflamed tonsil or by involvement of a group of lymph glands secondary to a tonsillar or postnasal infection These lymph glands are said to be present behind the pharynx in children, but to disappear in later life Acute retropharyngeal abscess constitutes a surgical emergency and may demand immediate operation to save life. Its diagnosis is more often missed than that of any of the dangerous conditions commonly encountered in the surgery of children, not excepting acute intussusception The patient is most commonly a pale debilitated child who may or may not be suffering from obvious dyspnœa The mother will probably say that for two or three weeks she has noticed that he has gone off his feed, dribbled a lot, or even regurgitated food which she thought he had swallowed. She will usually describe unwillingness to take food and does not realise that her baby either cannot swallow or else has experienced such pain and respiratory distress on attempting to do so that he has given up trying Dysphagia is only sometimes present, but dyspnœa in invariable Most mothers regard food as more important than air and hence the respiratory symptoms are quite unjustly often given second place The child "snores" (snoring is not common in babies), "goes black in the face when he cries," or "makes a rattling noise when he breathes" Sometimes a swelling of the neck will have been noticed, but the most common maternal diagnosis is "croup"

In any case if there is nothing pathognomonic in the picture, there should be enough to suggest that the child is suffering from an obstructive dyspnœa. If students were taught always to think of retropharyngeal abscess, and always to feel for it, in every case of obstructive dyspnœa, it would be less often passed over as "glands" or sent to fever hospitals as "laryngeal diphtheria" The finger is the final test Until the examiner has palpated the posterior pharyngeal wall, and thus incurred the noisy wrath of the infant and the silent reproach of the parent, he cannot exclude a retropharyngeal abscess The index-finger passed backward through the arch of the fauces of a normal child comes upon the bodies of the cervical vertebræ covered by prevertebral fascia and pharyngeal mucous membrane Upwards and downwards as far as the finger can reach there is a sensation of smooth hardness, much as is to be felt along the subcutaneous surface of the tibia If an abscess is present it may be seen with the aid of a tongue depressor, but the finger is the more reliable guide because the abscess may be too low to be visible Instead of uniform hardness a boggy swelling is felt on one side of the mid-line immediately behind the posterior pillar of the fauces Its size varies from that of a hazel nut to a bantam's egg, and its consistency suggests an over-ripe plum The finger in the baby's pharynx is of equal importance to the finger in the adult s rectum, and often gives more information It only remains to be added that large abscesses may be ruptured in this way unless the greatest care and gentleness are used The treatment may be considered under three heads · (1) immediate or operative; (2) post-operative; (3) removing the primary focus

Operative Treatment

Operation consists in opening and evacuating the abscess cavity which lies behind the pharynx and in front of the prevertebral fascia almost invariably to one side of the mid-line The difficulties and dangers associated with such a simple procedure are due to the position of the abscess at the inlet of the respiratory tract, the necessary precautions are directed to the maintenance of an open airway

The patient is placed in the dorsal position on the operating table with a sandbag under the shoulders The head is extended as far as possible and the end of the table is lowered to lessen the risk of pus being aspirated into the lungs The surgeon sits at the patient's head A good light, though not essential, adds precision to the final stages of the operation If an overhead multiple-reflecting lamp is not obtainable, the Milsom-Davidson tonsil lamp is an excellent and portable substitute Many operators prefer to use no anæsthetic, and only light open ether is permissible The mouth is gagged open as widely as respiration permits and the tongue seized with spiked forceps A scalpel, guarded by adhesive plaster except at its distal quarter inch, is plunged into the wall of the abscess and at once withdrawn There is an immediate rush of pus varying in amount with the size of the abscess If the mouth and pharynx immediately fill, the surgeon should use gravity to the fullest extent by asking an assistant to lift the patient by the legs, he meanwhile controlling the head and assisting gravity by rapidly swabbing out the pus Adults or large children must be turned on the same side as the abscess Respiration will proceed unimpeded when the first rush of pus has subsided, and the operation may be completed at leisure. It is now that an anæsthetic is useful. The incision is enlarged if necessary to admit the tip of a finger, and the abscess cavity is digitally explored The opening must extend down the pharynx to the limit of the cavity, the importance of this step is second only to that of safeguarding the child's life in the first part of the operation This downward extension of the incision is best accomplished by the finger and sometimes requires a little force Finally, a thorough inspection is made of the cavity, which is cleaned with ribbon gauze and left open The patient is returned to bed and if ether has been given he is placed upon his side until consciousness returns, then moved to the sitting position and kept there If no anæsthetic is used he should be sat up immediately the operation is finished Sometimes it will be necessary to consider immediate operation either in the patient's house or the doctor's surgery Although the practitioner may quite fairly be anxious to get the child into hospital or into the hands of a surgeon he should not hesitate to operate himself if he thinks the unavoidable minimum of delay is likely to be dangerous In making this decision, he should be guided by the degree of respiratory embarrassment present and the rate at which it is progressing If the child does not seem to have become worse during the last few hours it will probably be safe to wait until further arrangements can be made Any cyanosis must be taken as a danger signal demanding immediate operation because small children are most intolerant of even slight degrees of asphyxia It must not be thought, however, that cyanosis is the key to the decision as it occurs late and the real danger is syncope rather than asphyxia If immediate interference is necessary, the doctor should rapidly perform the operation described above with such modification as circumstances may dictate Tracheotomy should never be necessary.

When treatment is undertaken in the casualty or out-patient department of a hospital, the patient ought, if possible to be admitted for at least one night after operation

It may be thought that in these enlightened times, with our aspirating needles and evacuating motors, we need no longer have recourse to such mediæval practices as are implied by guarded scalpels and holding patients upside down It is doubtful, however whether modern methods or instruments have contributed anything to this particular operation. Moreover, the mechanical factor is sometimes less reliable than the human, and a momentary hitch may be a very serious matter for a child undergoing operation for retropharyngeal abscess

Post-operative Treatment

The ordinary acute case is well in from three to five days, but about half the patients will require treatment in bed for a longer time The commonest complications are septic bronchitis, broncho-pneumonia, refilling of the abscess cavity, and mediastinitis The best treatment of all four complications is prophylaxis during the operation, and it is doubtful how far drugs are effective either in the primary condition or its complications If a local application is used after operation, chloramine ½ per cent as a throat spray is satisfactory, and a mixture containing ammonium carbonate and ipecacuanha is usually given for bronchitis If the abscess cavity refills it is nearly always because the incision has not been carried low enough and this must be corrected at once

It is remarkable that some of these patients after operation will suffer from diurnal fever up to 104° F. and yet make a gradual and complete recovery, even though high fever may have persisted for a long time—e g, 39 and 21 days

Removing the Primary Focus

The infecting organism is almost always the streptococcus, and its port of entry the tonsil As soon as the patient has recovered from his acute illness the tonsils must be dissected and the adenoids removed In retropharyngeal abscess, as in acute mastoiditis, a slow convalescence can sometimes be surprisingly hastened by a timely removal of the primary focus When a small abscess is present, it is sometimes good practice to remove the tonsils and adenoids at the same time as the abscess is evacuated The youth of the patient is no bar to the removal of tonsils and adenoids if Waugh's method be used A retropharyngeal abscess left to itself will probably kill the patient, nevertheless it is a disease amenable to surgery of the simplest kind, and demands only a careful attention to detail to give the most satisfactory results Sudden deaths, however, do occur, and although the mortality after operation is probably less than 5 per cent, the prognosis must always be guarded

ERIC I LLOYD, M B, B Ch Camb, F R C S Eng,
Surgeon to the Hospital for Sick Children,
Great Ormond street

LADIES' COMMITTEE AT ST GEORGE'S HOSPITAL—Princess Marie Louise presided recently at the inaugural meeting of the Ladies' Committee which has just been formed to help St. George's Hospital It was announced that Mr Bernhard Baron had given £5000 The hospital is in need of a good supply of radium, about £2000 worth being required

EXTENSION OF MANSFIELD HOSPITAL—Plans have been approved for the enlargement of Mansfield and District Hospital at a cost of £50,000, of which £10 000 has been given by the Bolsover Colliery Company and £5000 by the Sherwood Colliery Company The extensions will increase the number of beds from 112 to about 180 The institution serves a population of 150 000, which is rapidly increasing in consequence of the development of the North Nottinghamshire coalfield

Special Articles.

THE TREATMENT OF VENEREAL DISEASES

MEETING AT CAMBRIDGE

THE first provincial meeting of the Medical Society for the Study of Venereal Diseases was held at Cambridge on Jan 29th Sir HUMPHRY ROLLESTON, President of the Society, took the chair and opened the proceedings with an address on

SPECIALISM IN MEDICINE

The Society, he said, confined its energies to the medical aspects of a most important cause of individual disease and of national deterioration The question whether or not specialism was good or bad for medicine as a whole had been settled long ago, but with the birth of each new specialty there was always a feeling of reluctance of the parent body to part with its offspring There was, of course, a good deal to be said against the progressive disintegration of medicine entailed by the segregation of those specially interested in a particular organ or part of the body, for eventually, if carried to its logical conclusion, the mosaic of general medicine might be so broken up as to bring about a reversion to the state of affairs in ancient Egypt about 500 B C, when each disease had its own expert who did not concern himself with anything else

With the ever-increasing scope of medicine and surgery the evolution of specialism had kept pace, first came special hospitals, such as the Royal Ophthalmic Hospital, Moorfields (1804), the Royal Hospital for Diseases of the Chest (1814), the Royal Ear Hospital (1814) then special departments at general hospitals were started and were officered by their own general physicians and surgeons The special hospitals had naturally been first in the field with medical officers who confined their activities to the diseases treated at the hospital, but he could remember the time when nearly all the surgeons at the Royal Ophthalmic Hospital were general surgeons on the staff of teaching hospitals

What were the reasons, asked the President, which should weigh in deciding what was and what was not a real and legitimate specialty? The amount of special knowledge and experience must be so considerable as to make it extremely difficult, if not impossible, for a general physician, surgeon, or practitioner competently and conscientiously to undertake the work and responsibilities in addition to his other manifold duties The second and probably the more important criterion was the degree of technical skill required for discharge of the methods of diagnosis and treatment of the conditions constituting the particular branch of medicine or surgery In the early treatment of venereal disease, if it was to be efficiently carried out, the technique demanded considerable training and experience, and, in order to maintain the standard consistent with the best results, constant practice was essential A third reason for the establishment of a specialty was to counteract, in the interests of the public, the activities of irregular practitioners for any branch of the healing art which did not greatly interest the majority of medical men was likely to be neglected, and as a result there was an opening for irregular practitioners In no branch of medicine was there more danger than in venereal disease that members of the public would resort to advertising quacks

The real function of a specialty was essentially to facilitate intensive study of the subject and to perfect technique Those working in special departments, therefore, were leaders and courts of appeal for the rank and file of the profession, who necessarily had to deal with the bulk of the patients To recall this might not be out of place in the light of the dictum of a practitioner, probably irritated by the real or fancied loss of his clients, "Never send a patient to a specialist" "Specialist" and "consultant" were not quite synonymous terms in practice, though the specialist was much the same as a consulting surgeon in operating on patients whereas a consulting physician's activity was usually limited to prescriptions and verbal advice The true and most beneficial function of a specialist was of course, to be the guide and co-worker of the medical practitioner, and not to take his place entirely

Relation of Syphilology to Other Specialties

Venereal disease in the past, continued the President, had been more closely allied with what, in contra distinction to internal medicine, the province of the physician, might be called external medicine—namely, surgery and especially urology, so that genito-urinary departments had undertaken the treatment of syphilis and gonorrhœa More recently dermatology, which more justly deserved the title "external medicine," had taken syphilis under its wing, as was shown by the names of various journals such as the *British Journal of Dermatology and Syphilis* Syphilis—which obviously had important relations with dermatology, as it had with all organs of the body—had thus been separated from gonorrhœa, which had so few connexions with dermatology This was an artificial distinction, as it separated two diseases of venereal origin The position of venereal disease as a special branch of medicine based particularly on ætiological considerations was rather different from that of other specialties which dealt with the disorders, whatever their nature, of an organ, locality, or system Further, the late results of syphilis, which might occur in practically every tissue and part of the body, brought it into close relation with all the divisions of medicine But these late results of syphilis should be under the care of the general physician, surgeon, or practitioner rather than exclusively of the specialist in venereal diseases On the whole there was more to be said in favour of allying venereal diseases with genito-urinary disease as a comprehensive specialty than for their association with dermatology With some familiar exceptions gonorrhœa and syphilis in their early stages were local lesions on the genitals and so must be distinguished from non-venereal diseases in the same region, and the complications of gonococcal infection mainly came within the scope of genito-urinary surgery But genito-urinary workers had comparatively recently (1920) united with those interested in the medical diseases of the kidney to form a section of urology at the Royal Society of Medicine, so that there was an opportunity for a triple alliance and extended team-work

The study of venereal disease, said the President in conclusion, could not be a subordinate part of any other specialty, for this would narrow its outlook and activities, it demanded intensive work, special technique, and thus, as the special departments and clinics for venereal diseases at the hospitals and under the Ministry of Health showed, had won its place as a recognised specialty The opportunities for research were most attractive and its potentialities for good in improving the national health must appeal to all who had humanitarian and sociological ambitions

After the President's address two films dealing with gonorrhœa and three films on syphilitic infection and the technique of its diagnosis were shown by Lieut-Colonel L W HARRISON Before showing his films Colonel Harrison said that the primary object of the demonstration was to popularise a method of teaching by cinematograph demonstration

Gonococcus and Streptococcus

Dr CHARLES SEARLE described three cases of septicæmia which arose after gonococcal infection This form of septicæmia, he said, was commoner in men than in women, and in pregnant than in non-pregnant women, and was more often responsible for fatal puerperal septicæmia than was, perhaps, generally realised, in fact, of the 6000 deaths every year in childbirth a very large proportion were from this cause Infection occurred through an abrasion of the mucous membrane which in a man might be due to the passage of a metal bougie Dr Searle then showed specimens from two single young girls of 20 years of age who came from the country

The first girl came in desperately ill and practically moribund with a temperature of 103° F, which was rather unusual in such cases She had been under treatment privately for six months for a vaginal discharge When he gave her the ordinary routine examination much to his surprise he found a foreign body in her posterior fornix which turned out to be a hairpin She admitted that she had run risks, but would not admit that in order to procure abortion she had inserted a hairpin which had actually penetrated into the bladder She died with streptococcal abscess in her kidneys and general septicæmia

The second girl first came to the clinic 15 months before her death, but ceased to attend before her course was completed Seen 15 months later she had chronic gonorrhœa and was ten months pregnant She had also a contracted pelvis which necessitated craniotomy Within 56 hours of her confinement she had a very slight rise of temperature, never much above 100°, and without much increase in pulse-rate, and she died of septicæmia after 20 minutes' unconsciousness

Dr Searle's experience was that they only found the gonococcus in one case out of 20, and that the gonococcus paved the way for the streptococcus There were several things they had to learn from those cases, it was quite certain that prenatal treatment would do a great deal to save such women if caught at an early stage The Society could do a great deal by propaganda among midwives and general practitioners, urging them to send any cases of possible gonorrhœa By 15 days' in-patient treatment they could very often cure these patients, but it was very difficult to tell whether they were clear or not In Cambridge they had not the proper facilities for dealing with these cases, nor the necessary lying-in beds

Dr J R C **Canney** thought that it had been rather lost sight of that the gonococcus made the way easy for the streptococcus to do its worst Of late a big move had been made to try to reduce the incidence of puerperal septicæmia, and some interesting work had been done with regard to the bacteriology of the vagina and cervix during pregnancy In quite a large proportion of pregnant women it had been found that virulent streptococci were actually growing in the cervical canal It was, therefore, not difficult to understand, if those conditions were present, why septicæmia was common He did not say that all such cases with infected genital tracts had previously been infected with gonorrhœa, but a very mild unrecognised attack of it might have been a predisposing cause in a fair proportion of cases

Colonel **Harrison** had long been convinced that the gonococcus was responsible for a good deal of puerperal septicæmia It had been found that in the venereal wards the maternity cases ran at a more level temperature than in the other wards of a maternity hospital He thought that was due to the fact that they had had antenatal treatment If beds were wanted locally, and they could prevail on the local authority to apply to the Ministry of Health they would find that the Ministry was very sympathetic

Dr D C **Logan** had been informed by one of the Ministry of Health inspectors of the venereal diseases block of the maternity hospital of which she was in charge that the morbidity was on the whole less than in the clean blocks of the hospital They usually got their cases at that particular hospital a good long time before confinement was due The hospital was associated with hostels and they often had the opportunity of getting the cases when the patients were only about five months pregnant In a large proportion of cases the gonococcus could not be found The clinical history was often suggestive and they found that a very large proportion of the cases they dealt with were originally gonorrhœal, secondary infection resulting in many cases On the whole they had been very fortunate, and she thought it was because they managed to get early treatment Where they did get temperatures they usually occurred among the cases which they had not had under treatment or observation for any long time

Dr D **Nabarro** said that he had great faith in the antenatal treatment of those cases It was astounding to him, when he first started that work to see the women who came up with tremendous discharges After they had been treated they cleared up and had a normal confinement He would like to urge that every town with a population large enough to support it should have a hospital for the treatment of such cases

After the meeting a dinner was held in the Old Library of Pembroke College at which Sir Humphry Rolleston presided, and some 30 to 40 members and their friends were present

IRELAND

(From our own Correspondent)

Paying Patients and Public Hospitals

The Department of Local Government and Public Health has recently circulated to county boards of health throughout the Free State a draft copy of regulations to cover the admission of paying patients to public hospitals For such patients to be admitted, regulations must be adopted by the county board of health and approved by the Minister. It is to be noted that in some counties it was one of the terms of appointment of the surgeon to the county hospital that he should be permitted to treat paying patients in the hospital, but in few areas regulations have been adopted to give legal sanction to this arrangement The draft regulations now issued are carefully framed They provide that a county board of health may set aside a ward or wards as paying wards, for the reception, maintenance, and treatment of persons not eligible for relief, that any person seeking admission to such wards must apply to the surgeon, or if he is absent, in case of urgency, to the matron, that any person so admitted shall pay a certain arranged sum for each day he is in hospital, together with appropriate additional charges for any special nursing or other expenses incurred in connexion with his treatment; that the surgeon may agree with such person as to the terms upon which he shall be treated, but that he shall out of any such sums received by him make good to the board of health any sums due by the patient to the board of health, and not paid to or recovered by the hospital, that the surgeon, if the patient so requires, shall permit any duly qualified medical practitioner to have access to such patient and shall, so far as possible, act in consultation with such practitioner

The draft regulations appear to meet the claims put forward on behalf of the medical profession at different times In particular, the provision which permits a paying patient to retain the services of his own doctor meets the objection, often raised, to the privileged position which the right to admit paying patients to a public hospital gives to the surgeon of the hospital With goodwill between the hospital surgeon and his medical neighbours the regulations should work well

The Training of Nurses

Miss K Price secretary of the Irish Nurses' Union gave evidence last week before the Commission on Technical Education She pointed out that where candidates had only national school education, the gap between the school-leaving age of 14 and the entry to hospital at 18 to 21 was injurious She suggested that the gap might be filled by a preliminary course in domestic service, hygiene, and physiology She thought the profession of nursing much overstocked in Ireland There was no general pension scheme for nurses and nurses had to continue working till they dropped Salaries were lower in Ireland than in England

CERTIFICATION OF THE CAUSES OF DEATH.

ISSUE OF A NEW MANUAL ON THE INTERNATIONAL LIST

The new manual of the International List of Causes of Death, as adapted for use in England and Wales, Scotland and Northern Ireland, has just been issued by the Stationery Office (1926 2s) The International List was revised at a conference held in Paris in 1920, but its publication was delayed until 1923 by the death of Dr Jacques Bertillon, Secretary-General of the Conference, and the present explanatory manual has taken another three years to prepare It has now been issued on the authority of the Registrars-General of the three countries with a view to providing for the use of public health officers, the medical profession generally, and any others interested, an official statement of the practice in force in the several parts of the United Kingdom with regard to the classification of causes of death The object of the manual is twofold (1) to ensure uniformity of practice in tabulation, and (2) to elucidate the precise significance of each title in the list by cataloguing the forms of death certificate assigned to it A similar manual has been issued for the United States of America The present British manual differs from its first issue in 1912 by various adaptations to local national requirements and by a revision of the rules followed in selecting a single cause for tabulation out of two or more recorded on the same death certificate The Health Section of the League of Nations is now making an endeavour to increase the comparability of the death statistics of the countries issuing the International List and the revisers of the manual have therefore considered the present time inopportune to make any considerable change They suggest, however, that the utility of an arbitrary code of rules in the tabulating department would be greatly affected if it were found possible for the death certificate itself to contain such indications as would enable the selection to be determined by the practitioner's own separate judgment

TABULATION OF CERTIFICATES AT THE HEAD OFFICE

The manual sets out the principles on which one cause is selected for statistical purposes when several causes are stated on the certificate The rules are not quite the same for all parts of the country In England, Wales, and Northern Ireland the general order of preference is as follows —

(1) Violence;
(2) Epidemic, Endemic, Infectious and General Diseases,
(3) Local diseases,
(4) Ill-defined causes of death

Selection when more than One Cause of Death is Stated

Violence —Where any forms of violence and disease are jointly stated as causes of death, the violence is to be preferred except in the following instances —

(*a*) Deaths from any definite disease stated to have been accelerated, aggravated, &c, by accident are to be classed to the disease

(*b*) Deaths during or resultant from operation or the administration of an anæsthetic are to be classed to the disease or injury for which the operation was performed

(*c*) Deaths from pneumonia or other lung diseases consequent upon accidental immersion are to be classed to the disease

(*d*) Deaths from injuries received during an epileptic or apoplectic fit are to be classed to epilepsy or apoplexy as the case may be

(*e*) Deaths from tetanus, erysipelas, pyæmia, septicæmia, blood poisoning, &c, following accident are to be classed to the disease if the injury was slight, such as "scratch" or 'abrasion," but if the injury was apparently severe enough to be of itself dangerous to life—e g, by vehicle, machinery, &c —the death is to be classed to violence

(*f*) Deaths from fracture occurring as a consequence of cancer are to be classed to cancer

Epidemic, Infectious and General Diseases —Any disease in these classes is to be preferred to any local disease except tabes dorsalis (locomotor ataxy), general paralysis of the insane, and aneurysm, which for this purpose are included with the general diseases in Group III and strangulated hernia and acute intestinal obstruction, puerperal sepsis and puerperal phlegmasia alba dolens not returned as septic which are included in Group I below The trifling exceptions to this rule are in regard to —

(*a*) Tumours not returned as malignant (brain and female genital organs excepted), diseases of the endocrine glands (diseases of the pituitary gland and adrenals and exophthalmic goitre excepted) which for this purpose are regarded as local diseases, and

(*b*) Thrush, undefined anæmia and chlorosis, chronic rheumatism and alcoholism, however stated, in view of the treatment of organic disease attributed to it which, for this purpose, rank below all except the ill-defined causes of death

The general diseases are divided into four groups in order of their importance for the purpose of selection. Any disease in Group I is to be selected in preference to any other not in Group I, any in Group II is to be preferred to any other not in Groups I and II, and so on If two or more of the diseases in any group are stated together the disease of longest duration or that first mentioned in the certificate, should as a rule be chosen

Group I —Small-pox, asiatic cholera, spirochætosis ictero-hæmorrhagica, acute poliomyelitis, encephalitis lethargica, meningococcal meningitis, epidemic hiccough, glanders, anthrax, rabies, tetanus, cancer (all forms), chronic poisonings by mineral and organic substances, strangulated hernia and acute intestinal obstruction, puerperal sepsis, puerperal phlegmasia alba dolens not returned as septic and other diseases of exceptional interest when occurring in this country, such as Mediterranean fever, plague yellow fever, leprosy, kala-azar, trypanosomiasis, pellagra, beri beri, &c

Group II —Enteric fever, typhus, relapsing fever (*Spirillum Obermeieri*), malaria, measles, scarlet fever, whooping-cough, diphtheria, dysentery

Group III —Influenza, mycoses (except thrush), tuberculosis (all forms), venereal diseases, rheumatic fever, diseases of the adrenals, tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm

Group IV —Mumps, erysipelas, German measles, varicella, purulent infection, septicæmia, chronic arthritis rheumatoid arthritis, osteo-arthritis gout, scurvy, rickets, diabetes, pernicious anæmia, diseases of the pituitary gland, exophthalmic goitre, leukæmia, lymphadenoma, other general diseases

If one of the causes mentioned is an immediate and frequent complication of another, the primary disease should be preferred to its complication Some special rules apply to the headings congenital malformations, icterus neonatorum, premature birth, injury at birth, "other diseases peculiar to early infancy" Under 3 months these conditions are to be preferred to any disease except syphilis and the diseases in Groups I and II Over 3 months any definite disease not presumably the consequence of a congenital defect is to be preferred to these conditions Premature birth is to be preferred to the other conditions enumerated At the other end of life, congenital debility and sclerema and senile decay are to be treated as ill-defined causes of death Lack of care is to be treated for this purpose as a form of violence Senile dementia is to be treated in the same manner as other forms of insanity

Local Diseases —The following are to be selected in preference to any other local diseases except tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm, strangulated hernia and acute intestinal obstruction and puerperal sepsis, phlegmasia alba dolens not returned as septic

(*a*) Malignant endocarditis, lobar pneumonia, infective enteritis and synonyms, parasitic diseases (except thrush), appendicitis, carbuncle, boil, cellulitis

(*b*) Other diseases of the spinal cord, cerebral tumour, other forms of insanity, epilepsy, idiocy, imbecility, senile dementia disseminated sclerosis, paralysis agitans,

A disease in (*a*) is to be preferred to any disease in (*b*) Where two or more local diseases, neither of which is included in the preceding list, are certified

together, that of longest duration should be preferred; if duration is not recorded any disease of a chronic nature should be preferred to a disease not so characterised; if neither disease can be assumed to be chronic, the first mentioned on a *medical* certificate should be selected Exceptions to this rule are as follows Any definite disease of the heart or kidney is to be preferred to any disease of the respiratory system "Congestion" of any organ, convulsions (non-puerperal), "hæmorrhage" without stated cause, laryngismus stridulus, and dyspepsia rank below all except the ill-defined causes of death Arterio-sclerosis, heart diseases, cirrhosis of the liver and chronic nephritis (including unspecified over 10 years of age) are to be preferred to cerebral hæmorrhage, apoplexy, &c, and hemiplegia which on the other hand are to be preferred to bronchitis Broncho-pneumonia, and pneumonia not otherwise defined, are to be preferred to bronchitis In the case of deaths occurring in mental institutions, nervous diseases are to be preferred to other local diseases, except those receiving special preference

Simpler Procedure in Scotland

In Scotland the rules are of a simpler character Preferences are to be applied in the order named and no one to be applied unless those preceding it are found inapplicable These preferences are as follows

1 Violence, except (*a*) trivial injuries combined with tetanus, erysipelas or septicæmia, (*b*) injuries received in epileptic or apoplectic fits and (*c*) deaths from anæsthetics during surgical operations

2 Infectious diseases, those of very low case mortality, such as chicken-pox, excepted

3 Diseases and accidents of pregnancy and parturition

4 More fatal diseases, such as cancer, tubercle, diabetes, Bright's disease, aneurysm, strangulated hernia, and intestinal obstruction Pneumonia to be preferred to bronchitis

5 A disease which is primary to one which is secondary Thus valvular heart disease is to be preferred to congestion of the lungs, pneumonia to meningitis, and many diseases to diarrhœa

6 Acute diseases are to be preferred to chronic

7 A disease named in the list of Causes of Death is to be preferred to one not so named but included in a general heading (e g, Other Diseases of the Respiratory System)

8 If none of the above preferences apply, the cause named by the certifier as primary is to be taken

FILLING-UP THE CERTIFICATE

The manual makes a number of suggestions to medical practitioners respecting certificates of causes of death It is regarded as highly desirable that medical practitioners should use in their certificates of death only those terms which are recognised in the nomenclature of the Royal College of Physicians of London When this is done, no difficulty is met with, generally speaking, in referring deaths to their proper heading in the International List of Causes of Death, as now adopted for use in the Registrar-General's Reports

Suggestions to Medical Practitioners

An alphabetical list is appended of unauthorised and indefinite or otherwise *undesirable terms* more or less commonly used in death certification, with comments indicating how the term is objectionable and what further information as to the cause of death is required in each case Some of these *terms are in* themselves objectionable as descriptive of the cause of any individual death, while others require to be supplemented in the manner indicated A few unobjectionable terms are included in the list for special reasons This list is intended for reference only, and it is hoped that it will be consulted by certifying practitioners in any case in which they are not assured that the term used by them is included in the nomenclature of the Royal College of Physicians

From the list of unauthorised or indefinite terms at present used on death certificates the following are selected from 133 examples given by the Registrar-General Suggestions of a similar character are issued to medical practitioners in Scotland

Examples of Undesirable Terms

Ref No	Indefinite or undesirable term *	Further information required (if available), and notes on the use of certain terms
1	Abscess	State cause (especially whether tuberculosis) and situation
6	Aortitis, arteritis, endarteritis	Was the condition due to syphilis? (If so, see No 118)
10	Blood poisoning	Variety of toxic condition present (pyæmia, septicæmia, &c), and cause of this condition
13	Cachexia	Disease causing this condition
21	Catarrh—	Term best avoided if possible
22	of bowels	Taken as equivalent to— Diarrhœa †
23	of lungs	Bronchitis †
24	of stomach	Gastritis †
27	Cerebro spinal meningitis	Cause of this condition Always certify "epidemic cerebro spinal meningitis" or "cerebro spinal fever," if this disease is meant
28	Childbirth	How this physiological process caused death
29	Cirrhosis of liver	Cause of this condition
33	Congestion of brain, kidney, liver, or other organ	If the disease amounted to an inflammation, use the appropriate term (lobar or broncho-pneumonia, acute or chronic nephritis, &c) Merely passive congestion should not be reported as a cause of death when the primary disease can be ascertained a cause of death when the primary
35	Croup	*Disease causing this condition, as diph*theria, laryngitis, laryngismus stridulus, &c Avoid using the word croup at all
43	Diarrhœa	Avoid certifying under this head in cases where the diarrhœa was merely symptomatic
48	Eclampsia	Disease causing this condition Was it puerperal?
57	General paralysis, paresis	If generaly paralysis of the insane is meant add the words "of the insane," and in all other cases indicate the disease causing the condition
59	Growth, new growth, tumour	Situation and nature of growth, if known If not known, add "nature unknown"
61	Hæmoptysis	Disease causing this condition Was it a case of tuberculous phthisis?
72	Lumbar abscess	Cause and site of origin Was it tuberculous?
73	Malignant disease	Taken as equivalent to cancer The word malignant should never be used in reference to any other disease, when such use may cause confusion with cancer
82	Nephritis	Acute or chronic? Was it associated with pregnancy? Did it result from scarlet fever or any other disease?
89	Papilloma of bladder	This tumour is listed under benign tumours by the Royal College of Physicians, and should not be applied to villous carcinoma
90	Phthisis	Avoid using this term without qualification as to nature Always state whether tuberculous
104	Pneumothorax	Disease causing this condition
106	Puerperal fever	Avoid the use of this indefinite term by stating the form of puerperal infection —e g, puerperal pyæmia, puerperal septicæmia, puerperal septic intoxication, puerperal phlebitis, &c
110	Rheumatic arthritis	Always state whether acute, subacute, or chronic
111	Rheumatism	
112	Rodent ulcer	Position of ulcer
113	Rubeola	Term best avoided, as it is used for both measles and German measles
117	Softening of brain	Cause of this condition (embolism &c) The term should not be applied to senile dementia nor to general paralysis of the insane
118	Specific disease	The word "specific" will always be understood in the sense of syphilitic
125	Teething	Disease causing death
130	Uræmia	Cause of uræmia Was it due to puerperal, post scarlatinal or other acute nephritis, chronic *Bright's* disease, &c?

* When used without further particulars indicated in Col 3

† The alternative form of statement is much to be preferred

In cases where an indefinite term has to be employed because more definite information is lacking it would be well to indicate this fact in the certificate The word *idiopathic* will be understood as indicating that the probable cause of the condition stated is unknown —e g, idiopathic atrophy, idiopathic convulsions, idiopathic peritonitis, &c

CERTIFICATION OF THE CAUSES OF DEATH

ISSUE OF A NEW MANUAL ON THE INTERNATIONAL LIST

The new manual of the International List of Causes of Death, as adapted for use in England and Wales, Scotland and Northern Ireland, has just been issued by the Stationery Office (1926 2s) The International List was revised at a conference held in Paris in 1920, but its publication was delayed until 1923 by the death of Dr Jacques Bertillon, Secretary-General of the Conference and the present explanatory manual has taken another three years to prepare It has now been issued on the authority of the Registrars-General of the three countries with a view to providing for the use of public health officers, the medical profession generally, and any others interested an official statement of the practice in force in the several parts of the United Kingdom with regard to the classification of causes of death The object of the manual is twofold (1) to ensure uniformity of practice in tabulation, and (2) to elucidate the precise significance of each title in the list by cataloguing the forms of death certificate assigned to it A similar manual has been issued for the United States of America The present British manual differs from its first issue in 1912 by various adaptations to local national requirements and by a revision of the rules followed in selecting a single cause for tabulation out of two or more recorded on the same death certificate The Health Section of the League of Nations is now making an endeavour to increase the comparability of the death statistics of the countries issuing the International List and the revisers of the manual have therefore considered the present time inopportune to make any considerable change They suggest, however, that the utility of an arbitrary code of rules in the tabulating department would be greatly affected if it were found possible for the death certificate itself to contain such indications as would enable the selection to be determined by the practitioner's own separate judgment

Tabulation of Certificates at the Head Office

The manual sets out the principles on which one cause is selected for statistical purposes when several causes are stated on the certificate The rules are not quite the same for all parts of the country In England, Wales, and Northern Ireland the general order of preference is as follows —

(1) Violence,
(2) Epidemic, Endemic, Infectious and General Diseases,
(3) Local diseases,
(4) *Ill-defined causes of death*

Selection when more than One Cause of Death is Stated

Violence —Where any forms of violence and disease are jointly stated as causes of death, the violence is to be preferred except in the following instances —

(*a*) Deaths from any definite disease stated to have been accelerated, aggravated, &c , by accident are to be classed to the disease

(*b*) Deaths during or resultant from operation or the administration of an anæsthetic are to be classed to the disease or injury for which the operation was performed

(*c*) Deaths from pneumonia or other lung diseases consequent upon accidental immersion are to be classed to the disease

(*d*) Deaths from injuries received during an epileptic or apoplectic fit are to be classed to epilepsy or apoplexy as the case may be

(*e*) Deaths from tetanus, erysipelas, pyæmia, septicæmia, blood poisoning, &c , following accident are to be classed to the disease if the injury was slight, such as "scratch" or ' abrasion," but if the injury was apparently severe enough to be of itself dangerous to life—e g , by vehicle, machinery, &c —the death is to be classed to violence

(*f*) Deaths from fracture occurring as a consequence of cancer are to be classed to cancer

Epidemic, Infectious and General Diseases —Any disease in these classes is to be preferred to any local disease except tabes dorsalis (locomotor ataxy), general paralysis of the insane, and aneurysm, which for this purpose are included with the general diseases in Group III. and strangulated hernia and acute intestinal obstruction, puerperal sepsis and puerperal phlegmasia alba dolens not returned as septic which are included in Group I below The trifling exceptions to this rule are in regard to —

(*a*) Tumours not returned as malignant (brain and female genital organs excepted), diseases of the endocrine glands (diseases of the pituitary gland and adrenals and exoph*thalmic* goitre excepted) which for this purpose are regarded as local diseases, and

(*b*) Thrush, undefined anæmia and chlorosis, chronic rheumatism and alcoholism, however stated, in view of the treatment of organic disease attributed to it which, for this purpose, rank below all except the ill-defined causes of death

The general diseases are divided into four groups in order of their importance for the purpose of selection Any disease in Group I is to be selected in preference to any other not in Group I , any in Group II is to be preferred to any other not in Groups I and II , and so on If two or more of the diseases in any group are stated together the disease of longest duration or that first mentioned in the certificate, should as a rule be chosen

Group I —Small-pox, asiatic cholera, spirochætosis *ictero-hæmorrhagica*, acute *poliomyelitis*, *encephalitis* lethargica, meningococcal meningitis, epidemic hiccough. glanders, anthrax, rabies, tetanus, cancer (all forms), chronic poisonings by mineral and organic substances, strangulated hernia and acute intestinal obstruction, puerperal sepsis, puerperal phlegmasia alba dolens not returned as septic and other diseases of exceptional interest when occurring in this country, such as Mediterranean fever, plague, yellow fever, leprosy, kala-azar, trypanosomiasis, pellagra, beri beri, &c.

Group II —Enteric fever, typhus, relapsing fever (*Spirillum Obermeieri*), malaria, measles, scarlet fever, whooping-cough, diphtheria, dysentery.

Group III —Influenza, mycoses (except thrush), tuberculosis (all forms), venereal diseases, rheumatic fever, diseases of the adrenals, tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm

Group IV —Mumps, erysipelas, German measles, varicella, purulent infection, septicæmia, chronic arthritis, rheumatoid arthritis, osteo-arthritis, gout, scurvy, rickets, diabetes, *pernicious anæmia*, *diseases of the pituitary* gland, exophthalmic goitre, leukæmia, lymphadenoma, other general diseases

If one of the causes mentioned is an immediate and frequent complication of another, the primary disease should be preferred to its complication Some special rules apply to the headings congenital malformations, icterus neonatorum, premature birth, injury at birth, " other diseases peculiar to early infancy " Under 3 months these conditions are to be preferred to any disease except syphilis and the diseases in Groups I and II Over 3 months any definite disease not presumably the consequence of a congenital defect is to be preferred to these conditions Premature birth is to be preferred to the other conditions enumerated At the other end of life, congenital debility and scleræma and senile decay are to be treated as ill-defined causes of death Lack of care is to be treated for this purpose as a form of violence Senile dementia is to be treated in the same manner as other forms of insanity

Local Diseases —The following are to be selected in preference to any other local diseases except tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm, strangulated hernia and acute intestinal obstruction and puerperal sepsis, phlegmasia alba dolens not returned as septic

(*a*) Malignant endocarditis, lobar pneumonia, infective enteritis and synonyms, parasitic diseases (except thrush), appendicitis, carbuncle, boil, cellulitis

(*b*) Other diseases of the spinal cord, *other forms of* insanity, epilepsy, idiocy, imbecility, cerebral tumour, disseminated sclerosis, paralysis agitans, senile dementia

A disease in (*a*) is to be preferred to any disease in (*b*) Where two or more local diseases, neither of which is included in the preceding list, are certified

together that of longest duration should be preferred if duration is not recorded any disease of a chronic nature should be preferred to a disease not so characterised, if neither disease can be assumed to be chronic, the first mentioned on a *medical* certificate should be selected Exceptions to this rule are as follows Any definite disease of the heart or kidney is to be preferred to any disease of the respiratory system "Congestion" of any organ, convulsions (non-puerperal) "hæmorrhage" without stated cause, laryngismus stridulus and dyspepsia rank below all except the ill-defined causes of death Arterio-sclerosis, heart diseases cirrhosis of the liver and chronic nephritis (including unspecified over 10 years of age) are to be preferred to cerebral hæmorrhage, apoplexy, &c, and hemiplegia which on the other hand are to be preferred to bronchitis Broncho-pneumonia, and pneumonia not otherwise defined are to be preferred to bronchitis In the case of deaths occurring in mental institutions, nervous diseases are to be preferred to other local diseases, except those receiving special preference

Simpler Procedure in Scotland

In Scotland the rules are of a simpler character Preferences are to be applied in the order named and no one to be applied unless those preceding it are found inapplicable These preferences are as follows·

1 Violence, except (*a*) trivial injuries combined with tetanus, erysipelas or septicæmia (*b*) injuries received in epileptic or apoplectic fits and (*c*) deaths from anæsthetics during surgical operations

2 Infectious diseases those of very low case mortality, such as chicken-pox excepted

3 Diseases and accidents of pregnancy and parturition

4 More fatal diseases, such as cancer tubercle, diabetes, Bright's disease, aneurysm strangulated hernia, and intestinal obstruction Pneumonia to be preferred to bronchitis

5 A disease which is primary to one which is secondary Thus valvular heart disease is to be preferred to congestion of the lungs, pneumonia to meningitis, and many diseases to diarrhœa

6 Acute diseases are to be preferred to chronic

7 A disease named in the list of Causes of Death is to be preferred to one not so named but included in a general heading (e g, Other Diseases of the Respiratory System)

8 If none of the above preferences apply, the cause named by the certifier as primary is to be taken

FILLING-UP THE CERTIFICATE

The manual makes a number of suggestions to medical practitioners respecting certificates of causes of death It is regarded as highly desirable that medical practitioners should use in their certificates of death only those terms which are recognised in the nomenclature of the Royal College of Physicians of London When this is done, no difficulty is met with, generally speaking, in referring deaths to their proper heading in the International List of Causes of Death, as now adopted for use in the Registrar-General's Reports

Suggestions to Medical Practitioners

An alphabetical list is appended of unauthorised and indefinite or otherwise *undesirable terms* more or less commonly used in death certification, with comments indicating how the term is objectionable and what further information as to the cause of death is required in each case Some of these terms are in themselves objectionable as descriptive of the cause of any individual death while others require to be supplemented in the manner indicated A few unobjectionable terms are included in the list for special reasons This list is intended for reference only, and it is hoped that it will be consulted by certifying practitioners in any case in which they are not assured that the term used by them is included in the nomenclature of the Royal College of Physicians

From the list of *unauthorised* or indefinite terms at present used on death certificates the following are selected from 133 examples given by the Registrar-General Suggestions of a similar character are issued to medical practitioners in Scotland

Examples of Undesirable Terms

Ref No	Indefinite or undesirable term *	Further information required (if available), and notes on the use of certain terms
1	Abscess	State cause (especially whether tuberculosis) and situation
6	Aortitis, arteritis, endarteritis	Was the condition due to syphilis? (If so see No 118)
10	Blood poisoning	Variety of toxic condition present (pyæmia, septicæmia, &c), and cause of this condition
13	Cachexia	Disease causing this condition
21	Catarrh—	Term best avoided if possible
22	of bowels	Taken as equivalent to— Diarrhœa †
23	of lungs	Bronchitis †
24	of stomach	Gastritis †
27	Cerebro spinal meningitis	Cause of this condition Always certify "epidemic cerebro spinal meningitis" or "cerebro spinal fever," if this disease is meant
28	Childbirth	How this physiological process caused death
29	Cirrhosis of liver	Cause of this condition
33	Congestion of brain, kidney, liver or other organ	If the disease amounted to an inflammation use the appropriate term (lobar or broncho pneumonia acute or chronic nephritis &c) Merely passive congestion should not be reported as a cause of death when the primary disease can be ascertained a cause of death when the primary
35	Croup	Disease causing this condition as diphtheria laryngitis, laryngismus stridulus, &c Avoid using the word croup at all
13	Diarrhœa	Avoid certifying under this head in cases where the diarrhœa was merely symptomatic
48	Eclampsia	Disease causing this condition Was it puerperal?
57	General paralysis, paresis	If generally paralysis of the insane is meant add the words "of the insane," and in all other cases indicate the disease causing the condition
59	Growth new growth, tumour	Situation and nature of growth if known If not known, add "nature unknown"
61	Hæmoptysis	Disease causing this condition Was it a case of tuberculous phthisis?
72	Lumbar abscess	Cause and site of origin Was it tuberculous?
73	Malignant disease	Taken as equivalent to cancer The word malignant should never be used in reference to any other disease, when such use may cause confusion with cancer
82	Nephritis	Acute or chronic? Was it associated with pregnancy? Did it result from scarlet fever or any other disease?
89	Papilloma of bladder	This tumour is listed under benign tumours by the Royal College of Physicians, and should not be applied to villous carcinoma
99	Phthisis	Avoid using this term without qualification as to nature Always state whether tuberculous
104	Pneumothorax.	Disease causing this condition.
106	Puerperal fever	Avoid the use of this indefinite term by stating the form of puerperal infection —e g, puerperal pyæmia puerperal septicæmia, puerperal septic intoxication, puerperal phlebitis, &c
110	Rheumatic arthritis	Always state whether acute, subacute, or chronic
111	Rheumatism	
112	Rodent ulcer	Position of ulcer
113	Rubeola	Term best avoided, as it is used for both measles and German measles
117	Softening of brain	Cause of this condition (embolism, &c). The term should not be applied to senile dementia nor to general paralysis of the insane
118	Specific disease	The word 'specific" will always be understood in the sense of syphilitic.
125	Teething	Disease causing death
130	Uræmia	Cause of uræmia Was it due to puerperal, post scarlatinal or other acute nephritis, chronic Bright's disease, &c?

* When used without further particulars indicated in Col 3

† The alternative form of statement is much to be preferred

In cases where an indefinite term has to be employed because more definite information is lacking it would be well to indicate this fact in the certificate The word *idiopathic* will be understood as indicating that the probable cause of the condition stated is unknown —e g, idiopathic atrophy, idiopathic convulsions, idiopathic peritonitis, &c

CERTIFICATION OF THE CAUSES OF DEATH.

ISSUE OF A NEW MANUAL ON THE INTERNATIONAL LIST

The new manual of the International List of Causes of Death, as adapted for use in England and Wales, Scotland and Northern Ireland, has just been issued by the Stationery Office (1926 2*s*) The International List was revised at a conference held in Paris in 1920, but its publication was delayed until 1923 by the death of Dr. Jacques Bertillon, Secretary-General of the Conference, and the present explanatory manual has taken another three years to prepare It has now been issued on the authority of the Registrars-General of the three countries with a view to providing for the use of public health officers, the medical profession generally, and any others interested, an official statement of the practice in force in the several parts of the United Kingdom with regard to the classification of causes of death The object of the manual is twofold (1) to ensure uniformity of practice in tabulation, and (2) to elucidate the precise significance of each title in the list by cataloguing the forms of death certificate assigned to it A similar manual has been issued for the United States of America The present British manual differs from its first issue in 1912 by various adaptations to local national requirements and by a revision of the rules followed in selecting a single cause for tabulation out of two or more recorded on the same death certificate The Health Section of the League of Nations is now making an endeavour to increase the comparability of the death statistics of the countries issuing the International List and the revisers of the manual have therefore considered the present time inopportune to make any considerable change They suggest, however, that the utility of an arbitrary code of rules in the tabulating department would be greatly affected if it were found possible for the death certificate itself to contain such indications as would enable the selection to be determined by the practitioner's own separate judgment

Tabulation of Certificates at the Head Office

The manual sets out the principles on which one cause is selected for statistical purposes when several causes are stated on the certificate The rules are not quite the same for all parts of the country In England, Wales, and Northern Ireland the general order of preference is as follows —

(1) Violence ;
(2) Epidemic, Endemic, Infectious and General Diseases,
(3) Local diseases,
(4) Ill-defined causes of death

Selection when more than One Cause of Death is Stated

Violence —Where any forms of violence and disease are jointly stated as causes of death, the violence is to be preferred except in the following instances —

(*a*) Deaths from any definite disease stated to have been accelerated, aggravated, &c , by accident are to be classed to the disease

(*b*) Deaths during or resultant from operation or the administration of an anæsthetic are to be classed to the disease or injury for which the operation was performed

(*c*) Deaths from pneumonia or other lung diseases consequent upon accidental immersion are to be classed to the disease

(*d*) Deaths from injuries received during an epileptic or apoplectic fit are to be classed to epilepsy or apoplexy as the case may be

(*e*) Deaths from tetanus, erysipelas, pyæmia, septicæmia, blood poisoning, &c , following accident are to be classed to the disease if the injury was slight, such as "scratch" or ' abrasion," but if the injury was apparently severe enough to be of itself dangerous to life—e g , by vehicle, machinery, &c —the death is to be classed to violence

(*f*) Deaths from fracture occurring as a consequence of cancer are to be classed to cancer

Epidemic, Infectious and General Diseases —Any disease in these classes is to be preferred to any local disease except tabes dorsalis (locomotor ataxy) general paralysis of the insane, and aneurysm, which for this purpose are included with the general diseases in Group III and strangulated hernia and acute intestinal obstruction, puerperal sepsis and puerperal phlegmasia alba dolens not returned as septic which are included in Group I below The trifling exceptions to this rule are in regard to —

(*a*) Tumours not returned as malignant (brain and female genital organs excepted), diseases of the endocrine glands (diseases of the pituitary gland and adrenals and exophthalmic goitre excepted) which for this purpose are regarded as local diseases, and

(*b*) Thrush, undefined anæmia and chlorosis, chronic rheumatism and alcoholism, however stated, in view of the treatment of organic disease attributed to it which, for this purpose, rank below all except the ill-defined causes of death

The general diseases are divided into four groups in order of their importance for the purpose of selection Any disease in Group I is to be selected in preference to any other not in Group I , any in Group II is to be preferred to any other not in Groups I and II , and so on If two or more of the diseases in any group are stated together the disease of longest duration or that first mentioned in the certificate, should as a rule be chosen

Group I —Small-pox, asiatic cholera, spirochætosis ictero-hæmorrhagica, acute poliomyelitis, encephalitis lethargica, meningococcal meningitis, epidemic hiccough, glanders, anthrax, rabies, tetanus, cancer (all forms), chronic poisonings by mineral and organic substances, strangulated hernia and acute intestinal obstruction, puerperal sepsis, puerperal phlegmasia alba dolens not returned as septic, and other diseases of exceptional interest when occurring in this country, such as Mediterranean fever, plague, yellow fever, leprosy, kala-azar, trypanosomiasis, pellagra, beri beri, &c

Group II —Enteric fever, typhus, relapsing fever (*Spirillum Obermeieri*), malaria, measles, scarlet fever, whooping-cough, diphtheria, dysentery

Group III —Influenza, mycoses (except thrush), tuberculosis (all forms), venereal diseases, rheumatic fever, diseases of the adrenals, tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm

Group IV —Mumps, erysipelas, German measles, varicella, purulent infection, septicæmia, chronic arthritis, rheumatoid arthritis, osteo-arthritis gout, scurvy, rickets, diabetes, pernicious anæmia, diseases of the pituitary gland, exophthalmic goitre, leukæmia, lymphadenoma, other general diseases

If one of the causes mentioned is an immediate and frequent complication of another, the primary disease should be preferred to its complication Some special rules apply to the headings congenital malformations, icterus neonatorum, premature birth, injury at birth, " other diseases peculiar to early infancy " Under 3 months these conditions are to be preferred to any disease except syphilis and the diseases in Groups I and II Over 3 months any definite disease not presumably the consequence of a congenital defect is to be preferred to these conditions Premature birth is to be preferred to the other conditions enumerated At the other end of life, congenital debility and sclerema and senile decay are to be treated as ill-defined causes of death Lack of care is to be treated for this purpose as a form of violence Senile dementia is to be treated in the same manner as other forms of insanity

Local Diseases —The following are to be selected in preference to any other local diseases except tabes dorsalis (locomotor ataxy), general paralysis of the insane, aneurysm, strangulated hernia and acute intestinal obstruction and puerperal sepsis, phlegmasia alba dolens not returned as septic

(*a*) Malignant endocarditis, lobar pneumonia, infective enteritis and synonyms, parasitic diseases (except thrush), appendicitis, carbuncle, boil, cellulitis

(*b*) Other diseases of the spinal cord, other forms of insanity, epilepsy, idiocy, imbecility, cerebral tumour, disseminated sclerosis, paralysis agitans, senile dementia

A disease in (*a*) is to be preferred to any disease in (*b*) Where two or more local diseases, neither of which is included in the preceding list, are certified

He added that its operations. at present restricted to East India goat hair and Egyptian wool, ought soon to be extended to other infected materials Factory and Workshops Acts Regulations of 1907 dealt with the handling of horsehair from China, Siberia and Russia as a dangerous industry: they prescribed disinfectants forbade anyone to work on non-disinfected horsehair with any open cut or sore ordered cautionary notices about anthrax to be posted up on the premises and contained the usual provisions about the wearing of overalls the reporting of cuts and sores washing, and restriction of keeping or eating food in rooms where such horsehair is stored or manipulated Regulations of 1908 as to factories in which East Indian wool is used do not go quite so far, but the more recent Hides and Skins Regulations of 1921 are more elaborate They relate to premises where are handled dry or dry-salted hides or skins imported from Africa (including Madagascar) or Asia (including Japan and the Malay Archipelago) A cautionary notice is to be posted and first-aid boxes special clothing mess rooms and lavatories provided Employees must report cuts and sores to their foreman and must not handle hides till their injury is treated In the Folkestone case a factory inspector said he was satisfied that all regulations had been complied with Anthrax is a scheduled industrial disease under the Workmen s Compensation Act for workers who have to handle wool hair, bristles hides and skins Thus if such a worker contracts it the disease is deemed due to the nature of his employment unless the employer can prove the contrary

Verminous Insects in Turkish Baths

A plaintiff who paid 5s for spending a night in some Turkish baths in London, sued the proprietors for damages for personal injuries alleging that he had been bitten by verminous insects. After hearing the evidence the judge was satisfied that the plaintiff had been bitten by bugs that he had not been bitten before going to the baths that he was bitten while in the baths, and that he had not himself carried the bugs there The defendants argued that there was no implied warranty that the plaintiff should not be bitten and that there was no negligence on their part as they had taken all reasonable steps to keep their premises free from verminous insects The judge however found them liable in law as well as in fact, and awarded £52 10s damages with costs on the High Court scale As a matter of contract, he considered the defendants had impliedly agreed with the plaintiff that the premises were reasonably fit for use as Turkish baths and incidentally that the couches were reasonably fit to recline upon The parties must have contemplated that the cubicles and couches should be free from bugs or other harmful insects If there was this implied contract, it mattered nothing what steps the defendants had taken to render their premises fit if the plaintiff was injured, it availed the defendants nothing, though they had taken every possible step Apart from contract the defendants owed the plaintiff a duty not to be negligent. The plaintiff was not a mere invitee, but a person who had paid money for the right to use the premises If the premises were unfit and the defendants knew it, and allowed the plaintiff to use them without warning him of the danger, then the defendants would be liable if the plaintiff was thereby injured The judge held that the proprietors of the Turkish baths knew of the danger (there was evidence of various complaints to the staff of the baths from other users) and allowed the plaintiff to use the premises without warning him. He held that the plaintiff had suffered damage to the extent already stated by reason of the breach of warranty and the negligence Evidence was given at the trial to the effect that iron bedsteads had been substituted for wooden ones since the complaint had been made The proprietors of Turkish baths will no doubt note this ruling as to their legal liability. At one point in the case it had been suggested that the bites were due to mosquitoes, but there was clear evidence to the contrary.

Colonel Kynaston's Case: Summons Withdrawn

When proceedings were taken against Colonel Kynaston late R A M C., under the Dangerous Drugs Act the gist of the charge was that he not being then a registered medical practitioner, had prescribed powdered opium A further summons was also taken out against him in connexion with the same transactions charging him under the Medical Act with having unlawfully, wilfully, and falsely used the descriptions M R.C S and L R C P. Lond. When the prosecution secured his committal on the Dangerous Drugs Act and his conviction and punishment by fine at the Old Bailey the Medical Act summons was not proceeded with, but was adjourned *sine die* Subsequently, the Old Bailey conviction was quashed by the Court of Criminal Appeal on the ground that the charge had named the Dangerous Drugs Act of 1925 and that the 1925 Act was not yet in force but the Medical Act summons remained outstanding At Marlborough-street police-court on Feb 7th the prosecution applied to the magistrate, Mr Cancellor for permission to withdraw the summons, which would not have pursued if the conviction had stood

---

THE CLOSING OF THE POST-GRADUATE HOSTEL.

A GENERAL *meeting of the vice-presidents and* supporters of the Post-Graduate Hostel was held at the Imperial Hotel on Monday Jan. 31st Sir D'Arcy Power President of the Hostel was in the chair, and there was a very poor attendance.

The Chairman reported that the financial basis on which the Hostel had been built up had failed. It had been expected that post-graduates would patronise the Imperial Hotel and its branches and thereby supply the Hostel, through the discount to be allowed by the hotel proprietors to the Hostel, with the income necessary for the carrying on of the discussions and the social activities of the Hostel. The Hostel had now been in operation for six months and although the discussions had been successful the number of people lodging in the Hostel had been very few and the Executive was now faced with a deficit of about £60, which was likely to increase unless a new financial basis were found for future operations He thought that probably the best way would be to bring the experiment to a close

After some discussion it was proposed by Dr. Andrew Balfour and seconded by Sir James Berry that the affairs of the Hostel be wound up. Both of them expressed their great reluctance in advocating this step but they felt that the encouragement received was not sufficient to justify the Executive in continuing It was probable that the locale of the Hostel had not been well chosen and at any rate it was certain that any experiment of the kind ought to have behind it either a sufficient capital sum to provide a really satisfactory hostel or a moderate but certain annual income if a smaller experiment were to be tried. The present movement had neither of these

Mr McAdam Eccles supported the motion, which was carried At the same time it was also resolved that a Committee, consisting of Sir D Arcy Power, Dr Andrew Balfour, Sir Thomas Horder the Honorary Treasurer and Dr Cox be appointed to wind up the affairs of the Hostel The proceedings closed with the cordial thanks of the meeting to Mr. A. P. Bertwistle, the Director of the Hostel for the great trouble he had taken and with a recognition of the success with which he had arranged interesting discussions

Most of those present dined together, and afterwards there was a meeting presided over by Sir Thomas Horder unfortunately with a very small attendance, to hear an address from Sir Arthur Robinson First Secretary of the Ministry of Health on Our Duty to

Primary and Secondary Causes.

By *primary cause of death* is meant (in the case of deaths from disease) the disease, present at the time of death, which initiated the train of events leading thereto, and *not* a mere secondary, contributory, or immediate cause, or a terminal condition or mode of death Acute specific diseases, if of recent occurrence, are to be considered the primary cause of death, even though the actual disease, as tested by power of infection, be no longer present at the time of death—e g, measles (primary) 12 days; broncho-pneumonia (secondary) 6 days In the case of deaths from cancer the seat of primary growth, even if this has been removed, should be stated if possible

A *terminal condition* or *mode of death* should not be entered as a secondary—i e, contributory—cause In a very large proportion of instances the statement of the primary cause gives all the information required; in these cases nothing is gained by adding as a secondary cause such a condition as syncope, heart failure, coma, exhaustion, &c Thus a certificate of pulmonary tuberculosis is not improved by addition of "exhaustion" as a secondary cause, though if a complication such as "pneumothorax" had supervened this should be noted as a contributory cause of death

In all cases "Yes" or "No" should be entered in the column headed *Post mortem* on the certificate

The Registrar-General will always be grateful to receive direct communications containing *information* as to causes of death which was not available when the certificate was issued These should be addressed to the Registrar-General, General Register Office, Somerset House, London, W C 2, and require no stamp Such information will not be incorporated in the record of the certificate, but will often be of the utmost value for statistical purposes If this course were adopted when the precise cause of death can be stated (in the light, for instance, of a post-mortem examination or of a microscopic or bacteriological investigation), many indefinite certificates could be correctly classified

Some Special Causes

In addition to the foregoing general considerations, the following points as to special causes of death call for attention —

(a) *Small-pox* —In certifying a death from small-pox the patient's condition with respect to vaccination should be carefully stated—say, in one or other of the following forms (1) No evidence of vaccination; (2) vaccinated in infancy only—number of scars (3) vaccinated only after infection by small-pox (4) stated to have been vaccinated, but no scars (If the patient has been revaccinated, the date should be given when possible)

(b) *Cancer* —Attention is particularly directed to the request that the seat of primary occurrence should be returned in all cases where known

(c) *Diarrhœa* —When this is due to improper feeding, or to any kind of food infection, the fact should be mentioned in the certificate The Royal College of Physicians having condemned the use of the terms *gastro-enteritis*, *muco-enteritis*, and *gastric catarrh* as alternatives for the authorised term "infective enteritis," it is hoped that the use of these italicised terms will be entirely discontinued

(d) *Childbirth* —Whenever parturition or miscarriage has been in any way a contributory cause of death, the fact should be mentioned on the certificates Always qualify all diseases resulting from childbirth or miscarriage as puerperal —e g, puerperal septicæmia, puerperal peritonitis, &c

(e) *Violence* —The term violence is understood as including all deaths from unnatural causes (including anæsthetics and poisons of all forms), whether accidental suicidal, or homicidal It is rarely the duty of medical practitioners to issue certificates in the case of deaths from recently sustained violence, but it must be borne in mind that if a coroner declines to hold an *inquest* upon such a death a medical practitioner who has attended the deceased is bound by Section 20 of the Births and Deaths Registration Act, 1874, to give a certificate of the cause of death When certifying deaths from violence which have not already been reported to the coroner (e g, *from* paraplegia due to violence sustained many years before death), medical practitioners should advise the friends of the deceased to inform that official forthwith

The following suggestions as to the form of certification of violent deaths are extracted from the Registrar General's Circular to His Majesty's Coroners (1911) —

> "In every case of death by violence or by suspected violence whether the death resulted from the violence itself or from a pathological state induced by it, the verdict should state the form and means of violence, its accidental, suicidal, or homicidal nature, and the nature of the injury—e g, fracture of skull (*nature of injury*) due to being *accidentally* run over (*form of violence*) by a motor car (*means of violence*)"

(f) *Operation* —In all cases where an operation has been performed for the disease or injury causing death, the operation as well as the disease or injury for which it was performed, and any secondary conditions contributory to death and resultant from the operation, should be mentioned on the certificate The interval between operation and death should also be recorded

(g) *Anæsthetics* —When death occurs during anæsthesia or is in any degree attributable thereto, the nature of the anæsthetic used should be recorded

The body of the manual is occupied by a tabular list under 205 headings, showing the terms included under each title of the detailed international list of causes of death as adapted for use in England and Wales, Scotland and Northern Ireland An index to the tabular list and alphabetical list of terms used in the certification of the cause of death occupies pages 50 to 135 and will be found invaluable for reference

MEDICINE AND THE LAW.

Anthrax Brush Factory Worker's Death

A VERDICT of death from anthrax was recorded on Feb 4th, at an inquest held upon the body of a boy employed in a Folkestone mop and brush factory He had developed a boil at the back of his neck, this was followed by a swelling as large as a man's fist in the front of the throat Subsequently, he was seized as with a fit, two doctors, called in just before he died, were unable to find the cause of illness Evidence at the inquest was to the effect that cultures taken from the spleen and from the carbuncle showed a typical growth of the anthrax bacillus The factory manager stated that the firm had obtained two lots of hair for making brushes The first consignment was English and Chinese horsehair, there were pig-bristles also from China, a small portion of the Chinese hair was in an open box in the room where the boy worked It was also stated that the factory premises were previously used as stables

Parliament has dealt with anthrax at several points In addition to the powers under the Diseases of Animals Acts, there is the Anthrax Prevention Act of 1919 and certain special provisions made departmentally under the Factory and Workshop Acts The 1919 Act authorised the prevention by Order in Council of the importation into the United Kingdom of goods infected or likely to be infected with anthrax The prohibition may be absolute or it may contain exceptions in favour of specified ports or be subject to specified conditions An Order in Council may declare goods which are of any specified class or origin, or which are exported from or through any specified country or place, to be goods likely to be infected with anthrax The first of these Orders prohibited the importation of Japanese shaving-brushes after Feb 9th, 1920 Another, in 1920, declared the following to be goods likely to be infected with anthrax All goat hair produced in or exported from or through India, all wool and animal hair produced in or exported from or through Egypt (including the Anglo-Egyptian Sudan) and all goods mixed therewith Importation of these is restricted to the port of Liverpool, and is subject to conditions as to labelling, prior notification and delivery to the Government Wool Disinfecting Station in that port Two years ago, in his book on "The Home Office" Sir Edward Troup wrote that this Liverpool Disinfecting Station, erected at a cost of £113,000, already pays its running expenses and gives excellent results

Obituary.

THOMAS ROBERT BRADSHAW, M D DUB, F R C P. LOND.

After a long illness, Dr T R Bradshaw died on Jan 25th at his home at Mold in North Wales, where he had lived since retiring from practice During the many years of his association with Liverpool hospitals he was recognised as a physician of real merit who brought to his work high qualities of mind and character

DR T R BRADSHAW

Born at Leamington in 1857, Thomas Robert Bradshaw was the son of John W Bradshaw, solicitor, of Dublin, and was educated in Dublin at the Rathmines Hospital and later at Trinity College He graduated M D in 1882, and later became M R C S Eng after a term of study at University College London His final settlement in Liverpool was largely due to the fact that his relative, the late Dr T H Waters was at this time physician to the Royal Infirmary and professor of medicine at University College in that city He first served as house physician and house surgeon at the Infirmary and at the Northern Hospital and was then elected successively to the honorary staff of the Stanley Hospital, the Northern Hospital and the Royal Infirmary This last appointment he held for 16 years In 1904 he was made a Fellow of the Royal College of Physicians of London

Dr Bradshaw wrote much on medical topics most of his papers appearing in the Liverpool medical journals The contributions to medicine which brought him most renown were perhaps those dealing with the morbid anatomy and pathology of myelopathic albumosuria The first observer in the English-speaking world (1897) to describe multiple myelomata occurring in conjunction with Bence-Jones albumose in the urine he was also the first to diagnose the condition correctly during life and was responsible for the hydrochloric acid test by which the protein is detected. His other communications dealt with subjects so widely diverse as cardiac murmurs, affections of the bronchi (on which he wrote for Quain's Dictionary of Medicine") the behaviour of litmus in amphoteric solutions Addison's disease and various neurological conditions He became lecturer in clinical medicine in the University of Liverpool and at one time examined for the University of London In 1910 the Liverpool Medical Institution elected him president In all his work there was evidence of literary taste as well as careful preparation and wide reading One of his chief interests was ecclesiastical architecture which he studied by taking excellent photographs

During the late war Dr Bradshaw worked for the First Western General Hospital He married in 1904 Rose Mary eldest daughter of Dr T R Glynn then professor of medicine in the University of Liverpool His widow survives him

JOSEPH JACKSON LISTER, F R S

Mr. Joseph Jackson Lister, who died on Feb 5th at his house in Cambridge was a nephew of Lord Lister and son of Arthur Lister, the distinguished botanist He was born in 1857 and was educated at St John's College Cambridge of which foundation he was a Fellow, and formed one of the group of young zoologists which made the Cambridge school of science famous 40 years ago to the immense benefit also of the school of medicine He was elected F R S in 1900 for his studies of the foraminifera, but his work was so much interfered with by his health that his qualities were little known outside an immediate circle but within that circle he enjoyed and rightly a high reputation both as man of science writer and colleague

JOHN HEDLEY M D DURH, L S A, J P.

Dr John Hedley, who died suddenly in London on Friday of last week of a heart attack, at the house of his son-in-law, Mr Douglas Harmer at the age of 84 years, had been the whole of his long life in general practice in Middlesbrough of which he was a worthy citizen

DR JOHN HEDLEY.

John Hedley was born at Ovingham Northumberland the youngest son of William Hedley and was educated privately at Stamfordham His father died when he was a boy and at the age of 15 years he was apprenticed to Dr James Aitchison of Wallsend taking at the same time a course at the Newcastle Medical School from which he qualified M R C S in 1864 and L S A in 1865 In the following year he began to practise in the town which was then little more than a large village and with the exception of a visit to France with the Red Cross in 1871 when he witnessed the surrender of Strasbourg, he practised continuously in Middlesbrough until his final retirement in 1918 He was soon appointed surgeon to the North Riding Infirmary and built up a large general practice on Tees-side often acting in a semi-official capacity as medical referee in compensation cases when his awards were accepted without demur as he was trusted by both sides He was himself certifying factory surgeon for the district only retiring from that post in his eighty-second year after an accidental fracture of his pelvis He assisted in a Home Office investigation into the epidemics of pneumonia in Middlesbrough and contributed an article to Oliver's "Industrial Diseases' After deciding in July 1914 to retire from active practice and enjoy some well-earned leisure he resumed his work again in November of that year, after war had broken out in order to release his successor for active service

He joined the Middlesbrough Town Council in 1886 was elected mayor in 1902 and held the office of alderman until two years ago He took the

Colonial Visitors Sir Arthur Robinson gave a most interesting account of the activities of the Ministry of Health in connexion with the subject of post-graduate education, which came in the nature of a surprise to most of those present He said it was unfortunate that his visit coincided with the closing down of the Hostel, but he felt sure that the effort had not been wasted and that the idea which had inspired the promoters of the Hostel could not die The time would undoubtedly come when London would provide a post-graduate school worthy of it and an essential part of that school must be a hostel which would attend to the social side

Those present passed a cordial vote of thanks for an address which the Chairman said had been really cheering on a depressing occasion

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg -Comdr W H Hastings is placed on the Retd List at his own request with the rank of Surg -Capt

The following appointments are notified Surg -Comdrs J P Shorten to *Princess Margaret* (on relief), B S Robson to *Sandhurst* (temp addl), and J C Souter to *Princess Margaret* (temp)

ROYAL ARMY MEDICAL CORPS

Col J W H Houghton, late R A M C , retires on ret pay

Maj W E C Lunn retires on ret pay and is granted the rank of Lt -Col

Capts to be Majs H A Sandiford, W D Anderton, C M Foster (Prov), H R Sheppard (Prov), and D W Beamish (Prov)

Capt D W M Mackenzie is restd to the estabt

Capt A Rodd is placed on the half-pay list on account of ill-health

Lts to be Capts W B F Orr, F T O'Meara, and T W Davidson (who remains secd)

ARMY DENTAL CORPS

Lt B Abbott to be Capt

ARMY RESERVE OF OFFICERS

Lt -Col A A Seeds, having attained the age limit of liability to recall, ceases to belong to the Res of Off

Lt A Robertson to be Capt

TERRITORIAL ARMY

Hygiene Companies —Maj J H P Fraser resigns his commn and is granted the rank of Lt -Col with permission to wear the prescribed uniform

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt -Col J F Dixon, having attained the age limit, relinquishes his commn and retains his rank

Col E F Buzzard, having attained the age limit, relinquishes his commn and retains his rank

TERRITORIAL DECORATION

The King has conferred the Territorial Decoration upon Majs J L Hamilton and A Morris, and upon Capt G B Tait

ROYAL AIR FORCE

Flight Lt G R Nodwell is transferred to the Reserve, Class D 1

Flying Officer V P Ellis (Temp Lt , General List, Army, Dental Surgeon) relinquishes his temporary commission on completion of service

INDIAN MEDICAL SERVICES

Capts Bindeshwari Prasad, J M Mitchell Codanda Madiah Ganapathy, and Nariman Jamshedji Gai to be Majs

Venkatachari Srinivasan and Hari Narain Gupta to be Temp Lts

Col A A Gibbs to be Maj -Gen , vice Maj -Gen W H Ogilvie, appointed Director, Indian Medical Service Capt L K Ledger is posted as Medical Officer and ex-officio Vice-Consul, Sistan The following are granted leave Col A W R Cochrane, Inspector-General of Civil Hospitals, United Provinces, Majs R Hay and E W Og Kirwan, Civil Surgeon, Mymensingh

DEATHS IN THE SERVICES

Fleet-Surg John Bellhouse Bowden Triggs, R N (retd) who died in a nursing home at Malden, Surrey, on Feb 1st, aged 75, graduated in medicine and surgery at Aberdeen University in 1873 and obtained the M R C S Eng in the following year He served during the Zulu War of 1879 in medical charge of H M S *Active* and in the Venezuelan revolution of 1891–92 (medal and diploma from the Venezuelan Red Cross Society for his services to the wounded)

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 29TH, 1927

Notifications —The following cases of infectious disease were notified during the week Small-pox, 532 (last week 558), scarlet fever, 1500 , diphtheria, 1030 , enteric fever 31 , pneumonia, 2618 , puerperal fever, 45 , puerperal pyrexia, 176 , cerebro spinal fever, 13 , acute poliomyelitis, 14 acute polio encephalitis, 3 , encephalitis lethargica, 26 dysentery, 11 , ophthalmia neonatorum, 108 There was no case of cholera, plague, or typhus fever notified during the week

The cases of small-pox were reported from the same counties as last week, with the addition of one case from Chester (Stockport), and one from Essex (West Ham)

Deaths —In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 50 (1) from measles, 6 (2) from scarlet fever, 101 (38 from whooping-cough, 43 (7) from diphtheria, 44 (12) from diarrhœa and enteritis under 2 years, and 725 (252) from influenza The figures in parentheses are those for London itself The influenza deaths for the last six weeks have thus been 69, 86, 173, 326, 470, and 725, while 818 is the figure notified for the week ending Feb 5th, the deaths in London being 215

INFLUENZA IN SCOTLAND

THE Scottish Board of Health states that up to Saturday last there was in most parts of Scotland no undue prevalence of influenza for the time of the year and nothing in the nature of an epidemic There was, however, a good deal of influenza of a mild catarrhal type, and in some places —Aberdeen, Greenock Falkirk, and the Lower Ward of Lanarkshire—it had increased since the previous week At Aberdeen about 3 per cent of persons visited by health visitors were found to have influenza and about 60 per cent of health insurance sickness benefit claims had reference to influenza cases In many other places there were fewer cases than in the previous week In Motherwell and Wishaw the type was reported to be becoming milder, and the interesting distinction previously reported by the medical officer of health that the symptoms of the Wishaw cases were mainly gastric and those of the Motherwell cases catarrhal was becoming less marked

ROYAL WEST SUSSEX HOSPITAL —A centenary fund has been inaugurated, and plans involving an outlay of £30,069 have been agreed upon for improvements Founded in 1784 as a dispensary for the relief of the sick poor, this institution became a hospital in 1703 and was established in 1826 as the Chichester Infirmary As it met the increasing needs of the district it came to be known as the West Sussex East Hants, and Chichester General Infirmary and Dispensary, and afterwards the word "infirmary" was deleted and "hospital" substituted King Edward frequently visited the hospital on his way from Goodwood to Cowes, and in 1912–13 the hospital was entirely renovated and reconstructed as a lasting memorial to him When on August 2nd, 1913, King George reopened the building, he acceded to the request that it should be known as the Royal West Sussex Hospital Nearly 1200 in-patients and three times that number of out-patients are nowadays treated yearly At the annual meeting in April, 1926, a contributory scheme was launched, and although it did not come into operation until November the number of contributors by the end of the year was over 5300, representing an income of over £2000 a year The success of this scheme seems thus assured, and already there has been a very encouraging response to the centenary appeal The new improvements to the hospital are to be associated with the name of the late Dr David Ewart

"Audi alteram partem."

DEATHS UNDER ANÆSTHETICS

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 22nd Dr. A. G. Levy adopts methods of deductive reasoning that cannot be passed by without comment. He assumes that a certain anæsthetic (ether) is safe: and this is reasonable enough, for it is commonly reputed to be so, and Dr. Levy himself has in the past done much valuable work on the dangers of its principal competitor. He collects from the Registrar-General the mortality due to its use and the mortality due to other anæsthetics, and finds that the statistical facts thus obtained do not bear out the theory of the almost fool-proof innocuousness of ether.

What, then, is his next step? To revise or reconsider the theory until it fits the facts? No. With sublime simplicity he alters the facts to fit the theory. The total yearly number of anæsthetic deaths has risen from 276 in 1911 to 446 in 1923 a rise of about 61 per cent. Part of this rise is accounted for by the ever-increasing number of operations. (The author estimates from the theatre statistics of a large hospital that this increase during the same period amounts to 13 per cent.) The casualty list yields the following information: chloroform deaths dropped from 66 per cent. to 22 per cent. Mixture deaths rose from 22 per cent. to 37 per cent. Ether deaths rose from 9 per cent to 32 per cent —this in spite of the increased popularity of the open ether method. In 1923, 123 deaths occurred from the use of ether alone; their records were examined and they were found to be mainly routine cases. Many of them were trivial, and there was no undue preponderance of excessively severe operations which might fictitiously swell the total.

But Dr. Levy's explanation of the rise in the number of deaths due to ether is that they are not in fact deaths due to ether at all. He states that, owing to the slowness of open ether induction, chloroform or a mixture is often used at first, followed by open ether. The administration is described as ether, mention of the preceding and possibly brief use of chloroform being omitted. Very likely this is so in some cases, but there is no proof that all or even many of the figures are inaccurate. As far as I can judge of the accuracy of the certification, the fact that the highest percentage of deaths is certified as due to mixtures inclines me to the belief that when a mixture is used the fact is revealed. The conclusion drawn at the end of the article is that the reports of the Registrar-General prove that diluted chloroform or a small amount of chloroform at the commencement of the induction is dangerous.

It may be so, but I cannot see how these figures, showing 32 per cent of ether deaths to 22 per cent of chloroform deaths prove it. It would surely be more rational, on finding facts that conflict with a theory, to re-examine the theory with a critical eye. Points worthy of investigation are (*a*) is ether so intrinsically innocuous as it is thought to be? (*b*) What is the effect of faulty or unskilled administration? (*c*) What is the effect of its use in unsuitable cases, under the belief that the (generally) safest drug is always the safest?

I have been much interested in this subject for several years, during which the impression has been gradually gaining ground in my mind that ether is more toxic and even more lethal than is usually thought. In order to test this hypothesis I have investigated a series of 30 000 cases an analysis of which is at present in the hands of the publishers. The results as I interpret them, show very clearly that by far the most important factor in the mortality-rate was the care taken in the administration. 10,000 cases from one hospital were compared with 20 000 from another. One hospital used chloroform freely (in 27 per cent of cases), even in closed inhalers, but insisted on skilled administration on all occasions The other hospital was chloroformophobic and nearly 95 per cent. of its patients received ether alone. Relying on the belief that ether is an innocuous drug anæsthetics were administered in many cases by unsupervised dressers The ether enthusiasts had a much higher mortality, both immediate and remote, than the careful chloroformophils, their deaths on the table being double and their remote mortality 23 times as great

While not attempting to attack the impregnable doctrine that ether is in general safer than chloroform, I do put forward the view that ether in unskilled hands is never fool-proof and may sometimes be dangerous. Personally, I would far rather have chloroform administered to me by an expert than ether by a novice.

I am, Sir, yours faithfully,

W. STANLEY SYKES.

Morley, near Leeds Feb 7th, 1927

THE FINGER-PRINTS OF IDENTICAL TWINS.

To the Editor of THE LANCET.

SIR,—In an annotation last week you referred to the close similarity, without actual identity of the finger-prints in a pair of identical male twins described by Dr. G. P. Crowden in the Guy's Hospital Reports. I went into this very point most carefully in a clinical lecture on Congenital Defects of the Long Bones, delivered in 1925 at Manchester University and printed in the *Journal of Bone and Joint Surgery* for July, 1925 It happened the identical twins there described were so similar that they reproduced a deformity—namely, absence of the tibia, shown by Hoffa's observations to be exceedingly rare. I therefore regarded my twins as especially similar—perhaps the most identical ever produced Their finger-prints were taken as 'probably identical,' but the Scotland Yard Department quickly found differences and established clearly their argument that no two impressions are alike. I am Sir, yours faithfully,

Manchester, Feb. 7th, 1927 ROBERT OLLERENSHAW.

IS THE PRESENT EPIDEMIC OF INFLUENZA DUE TO A STREPTOCOCCUS?

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 29th Drs. David and Robert Thomson have drawn attention to what they term an unusual streptococcus of a highly pleomorphic character. This organism was isolated from a case of apparently true influenza, and they suggest that the attack was caused by it May I point out that this pleomorphous streptococcus is not by any means a novelty? During the pandemic period of 1918-19 I was able to isolate this interesting organism from practically every case examined by me in Reading. The brothers Thomson will find a brief description of the streptococcus in THE LANCET for 1918 (vol. ii., p 722) and for 1919 (vol. i, p 280). If they care, further, to refer to my article on the Bacteriology of Influenza in Dr. F G. Crookshank's 'Influenza: Essays by Several Authors" (published by Messrs. Heinemann), they will find there references to papers from the pen of other bacteriologists dealing with an apparently similar organism. Whether it is the chief organismal factor in the causation of influenza is another matter. It may have no more claim to be so regarded than has Pfeiffer's bacillus, wrongly called the *Bacillus influenzæ*.—I am, Sir, yours faithfully,

ROBERT DONALDSON

St. George's Hospital Feb 2nd, 1927

To the Editor of THE LANCET.

SIR,—Drs. David and Robert Thomson state that they have obtained cultures of a streptococcus from one of themselves who was suffering from influenza. In this connexion it may be helpful to note that in liveliest interest in all that concerned the life of the town, became justice of the peace for the borough and county, a member of the Tees Conservancy Commission, served on insurance and education committees, and presided over the Committee of Selection for Magistrates

In 1873 Dr Hedley married May, elder daughter of Mr Edward Williams, then manager of Messrs Bolckow, Vaughan and Co, and with his wife's help he started soon after a nursing service for the workmen in the employment of her family, which developed later into the nursing association serving the town and district, one of the first of its kind in the country To the end of his life Dr Hedley retained the power of absorbing new ideas and applying them to practice, he was far in advance of his time in such matters as surgical cleanliness and the open-air treatment of disease, and to the end he kept in touch with the new medical knowledge of the time His wife predeceased him by two years Of his eight children, all of whom are living, two sons are in the medical profession and his two daughters married medical men

His funeral service was attended by the principal citizens of the county borough for which he had done so much, and which recognised that with his character and ability he might reasonably have aspired to a more imposing reputation on a wider stage. But he was content to begin and carry through to the end innumerable tasks which were of real service to the people among whom he lived

FRANCIS SORELL ARNOLD, M B, B CH OXF

WE regret to announce the death on Feb 5th, at Painswick, Glos, of Dr F S Arnold, after a short illness He was born in Dublin, grandson of Thomas Arnold, the famous Rugby headmaster, son of Thomas Arnold, the author of the well-known Manual of English Literature, and brother of Mrs Humphry Ward He was educated at Clifton, entering Christchurch, Oxford, with a junior studentship in 1879, and graduating there in natural science four years later He took his medical degrees in 1887, after spending four years at St Bartholomew's Hospital, and was for a time house surgeon at the Radcliffe Infirmary before taking up general practice For a period of seven years he was medical superintendent to the Hailey Open-air Sanatorium, utilising his experience there for a book on the "Modern Therapeutics of Pulmonary Phthisis" At Oxford he developed the polyglot capacity which stood him in good stead throughout his life, for he translated many foreign classics, and was equally at home with the Dutch, German, Spanish, and Italian languages The list of authors who owed him their introduction to English medicine is a long one, and includes the names of Bing, Schlesinger and Guelpa In past years THE LANCET has often been grateful to him for service of this kind More recently his professional life was spent at Berkhamsted, Bovingdon (Herts), and Painswick, where he was medical officer to a District Union and to the Guide Orphanage He married Annie, daughter of the late T R Wilkinson, who survives him By his death the medical profession loses a cultured member of many-sided interests

ROBERT WILLIAM FELKIN M D MARBURG L R C P, F R S EDIN

WE regret to record the death of Dr Robert William Felkin, a well-known student of tropical disease which occurred at Whare Ra, near Hawke's Bay New Zealand, on Dec 28th last Felkin was a Nottingham man and was educated at Wolverhampton He became interested at an early age from the religious point of view in the problems of anthropology and geography of disease, probably because he met Livingstone during childhood, and was much impressed by the career of that great medical missionary He received his medical education at Edinburgh, where he took the double qualification of the Royal Colleges He later obtained the medical degree of the University of Marburg, and shortly afterwards went with Stanley's expedition for the relief of Emin Pasha The life of that German traveller, physician and administrator as written by G Schneitzer, was introduced to English readers by Felkin, and it was easy to see that Africa possessed already a strong hold on his imagination He proceeded to Uganda, where he filled for some time the anxious post of medical advisor to a native king but finding little opening there for either his talents or his aspirations, he returned to England and worked at tropical diseases, the importance of whose study had now become manifest, though most of the modern pathology was still in the making Between 1890 and 1900 he made various visits to Africa the results of which he published in a work entitled the "Geographical Distribution of Tropical Disease," and he made many scientific communications to medical journals During this period he was an occasional though fairly frequent correspondent of THE LANCET both advising us when he was at home and communicating with us when he was abroad, but the greater part of his signed writing will be found in the *Balneological and Climatological Journal* For a period he lectured on tropical diseases in Edinburgh, and acted in a consulting capacity to the British Tropical Africa Company His health had been severely tried by his extensive travels, and after a definite breakdown he decided to reside permanently in New Zealand, where he passed the last 12 years of his life

Dr Felkin, though his name will always be associated with tropical disease, was a man of wide interests and knowledge He was a considerable anthropologist and a member of several foreign academies, he wrote on such various subjects as monism, heredity, and psychotherapeutics, and contributed papers to German and English publications on popular errors in medicine on folk-lore, and on spa treatment

LLEWELLYN POWELL PHILLIPS, M D CAMB, F R C S ENG, F R C P LOND

Dr Llewellyn Powell Phillips, who died recently in Cairo at the age of 55, was the son of a Cardigan physician, and was educated at Epsom and Caius College, Cambridge He obtained first-class honours in the natural science tripos of 1892 and went on to St Bartholomew's Hospital, graduating in medicine at Cambridge in 1895 and taking the F R C S Eng in 1897 After filling various residential posts at St Bartholomew's he proceeded to Egypt as resident surgical officer at the Kasr el Aini Hospital with which institution he was connected for 24 years as professor of clinical medicine in the school and senior physician to the hospital, his retirement from government service only taking place two years ago In 1909 he was elected F R C P

Dr Phillips was well known to all members of the medical profession whose business, or, indeed, whose pleasure, brought them into any relation with Egypt and especially with Cairo He had a large practice both among Europeans and natives for his energetic work done during a cholera epidemic in 1901 had secured for him the admiration of all the community During the war he acted as commandant of a British Red Cross hospital at Giza, where his wife acted as matron, and for his services he received honours both in the Medjidieh and Nile Orders

---

THE LATE DR A C ELLIOTT —The death is reported of Dr Arthur Campbell Elliott who had practised at St Annes-on-the-Sea Lancashire for 32 years Dr Elliott who was 61 years of age, graduated at the University of Edinburgh in 1891 and served as house surgeon at the Preston Royal Infirmary On entering general practice he became police surgeon for the St Anne's area and was medical officer to convalescent homes in the district There was a large gathering at the funeral on Jan 20th cancer cells in a few minutes by applying an appropriate antiserum, while controls in normal serum migrate actively for 2–3 weeks This is regarded as evidence that the antiserum tested was toxic —T L

TREATMENT OF TUBERCULOSIS BY MR SPAHLINGER'S METHODS

We have received a further letter from Mr Spahlinger, in which he repeats that he did not allude to "serum" when certain cases were under treatment at St George's Hospital, and states that he did not make the claims attributed to him for rapid results He says the cases treated outside the hospital were visited with him by Dr Linnell and Dr Hunt, but that they were not Dr Latham's cases, although they were seen by two of the staff of St George's Hospital on behalf of Dr Latham Mr Spahlinger acknowledges the amount of space already taken up by the controversy with gratitude and disclaims a desire for further polemics Nothing in his letter alters the position as set out by the correspondence which appeared in our columns on Jan 29th, 1927

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

OPENING OF SESSION—KING'S SPEECH

THE new session of Parliament was opened by the King in State on Tuesday, Feb 8th. In the course of the Speech from the Throne it was stated among the measures to be dealt with during the coming session would be a Bill to amend the law relating to industrial disputes , a Bill for the amendment of the law relating to leasehold premises, so as to secure to an outgoing tenant compensation for the loss of his good-will and unexhausted improvements , and Bills dealing with questions affecting agriculture and insurance against unemployment

HOUSE OF COMMONS.

TUESDAY, FEB 8TH

Poor-Law Reform and the Factories Bill Postponed

Speaking in the debate on the Address in reply to the Speech from the Throne, Mr BALDWIN, Prime Minister, said he thought that when the Speech was examined the House would see that there was a great deal of useful work that they might accomplish in the time at their disposal The Government had only put into the Speech such legislation as they thought there was a reasonable prospect of carrying by August 1st One measure of which the House had heard a good deal—namely, that dealing with Poor-law reform—was so large and comprehensive that it would have been impossible to take it this session unless they had contemplated a long autumn session. It was a measure which must be mixed up with very important and intricate questions of local finance It was very important that such questions should not come before the House until they had been examined from every point of view, and some opportunity had been taken of discussing them with local authorities He hoped that it might be possible when the new Session started in November to move ahead with this important piece of work The same was true of the Factories Bill

MANCHESTER ROYAL INFIRMARY —Plans have been approved for the erection in York-place of the new home for nurses and it is hoped that building will begin in a few months The total sum received for this purpose is £58,401 The accommodation required in the new home shows that a total staff of 379 has to be housed, including 85 domestic servants The number of cases treated in the accident room increased from 19,491 in 1922 to 26,347 in 1925, and 27,677 in 1926, the daily average of new casualty cases being just over 75 The ordinary income was £93,163, and the total ordinary expenditure £121,365 The deficits for the past three years have been—in 1924, £24,147 , in 1925, £22,740 , and in 1926, £18,082 The total number of patients treated rose from 57,499 in 1925, to 59,232 in 1926 There were 9657 operations performed Owing to the coal dispute, the extra expenditure on coal during the year was £5000

Medical News.

UNIVERSITY OF OXFORD —At a congregation held on Jan 27th the following degrees were conferred —

Bachelor of Medicine —William Frederick Howson Ray, Richard Christie Hodges, Robert Illingworth, Charles Webley Hope Gill, Thomas Mortimer Ling, George Eric Macdonald, Edward Mandeville Wright, William Dunstan Boileau Read, Charles Leo Harding, John G A. Davel, Arthur Harold Gale, Leslie Owen Frank Fysh, Robert Gordon MacGregor, Reginald Arthur Haythornthwaite, and Rosaleen Louise Graves

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND —Licences to practise have been conferred upon 46 candidates (9 women and 37 men) who have completed the final examination in medicine, surgery, and midwifery of the Conjoint Board and have complied with the by-laws of the Colleges This list is supplementary to that published in THE LANCET (Feb 5th, p 315) The following are the names and medical schools of the successful candidates —

Gertrude Alphonso, Calcutta and Royal Free R Andrews, London , N Attygalle, Ceylon and Middlesex , R Bandyopadhyay, Calcutta and St Thomas's , H Berliner and Augusta J Blumenthal, Univ Coll , H J Burrows, Cambridge and St Bart 's , R W Butler, Cambridge and St Thomas's , Mildred Carpenter, Univ Coll , A Carr, Guy's B Chaudhuri, Bombay and Middlesex , Pamela M G Churchill, King's Coll , F H N Cruchley, London , A S El-Katib, Cairo and St Thomas's , V Freeman, Univ Coll , H J Gubbin St Bart 's V F Hall, King's Coll , E O Harris Middlesex , J W O Holmes, St Bart 's, S G Irlam London , Freda C Kelly, Univ Coll , A E Kingston Middlesex , J S Lewis, St Mary's , E M Lourie, Univ Coll , R W L May, Cambridge and St Thomas's , Helen E Mayfield, St Mary's J L Newman Cambridge and King's Coll F G Parker Oxford and Guy's , Muriel V Paton, Royal Free , G C Pether, Middlesex , R K Pillay, Madras and London E N Price St Mary's , L J Rae, Cambridge and London , R H Rattray, Charing Cross, E R Rees St Bart 's , W Rosenberg Witwatersrand and Guy's , R Rutherford King's Coll , M Schwartz, Cardiff and Univ Coll , Helen D S C Scott, Royal Free and Charing Cross S Segal, Oxford and Westminster , M Shaw, Guy's , E S Vergette, St Bart 's D P Wailling, Bengal and St Thomas's L A F Wiles St Thomas's Marian E Williams, Royal Free , and R M Williams, Guy's

The following candidates were approved in the undermentioned subjects, but are not eligible for diplomas —

Medicine —Edna E Adams, Birmingham , Florence M. Allen, King's Coll H W Allen and C J Bashall St Thomas's , Constance M H Bishop, Charing Cross , W J Branday, Birmingham I G Briggs, London C F Brockington, Guy's , W G Brookes, Liverpool W A. 1919, on page 68 of his monograph entitled "Die Spanische Grippe und ihre Bekampfung" (published by E. Bircher, Berne), Dr Carl Spengler, of Davos, and formerly of the Koch Institute, described a streptococcus form of his "grippe bacillus," cultures of which he obtained from cases of influenza Drawings of this streptococcus are shown in the plates at the end of Spengler's monograph

I am, Sir, yours faithfully,

WALTER H. FEARIS,

Late Bacteriologist to the City of Cardiff and County of Glamorgan Public Health Laboratory

Brightlingsea, Feb 2nd, 1927

THE ADRENAL BODIES AND THE SPLANCHNIC NERVE.

To the Editor of THE LANCET.

SIR,—It has been shown by Pearlman and Vincent, Sheen and Vincent and Vincent and Wright that, when the peripheral end of the splanchnic nerve (in an animal under ether anæsthesia) is stimulated, the blood-pressure curve obtained is not a simple one. The initial rise of blood pressure is followed by a "dip" succeeded by a return to a level exceeding the initial height of the blood pressure, which height is maintained so long as stimulation is continued This dip does not recur after elimination of the adrenal bodies

MacDonald and Schlapp have recently demonstrated that the well-known depressor effect of small doses of adrenin is not due to any reversal of the action of the drug in such doses, but solely to a pharmaco-dynamical influence of the ether employed as anæsthetic This conclusion, if confirmed, removes at once one of the strongest arguments (frequently used by one of us) against the so-called "tonic" theory of adrenal activity This is obviously a matter of great clinical and pathological importance It is, therefore, satisfactory to record that we have been able fully to confirm the observations of MacDonald and Schlapp

It was believed by the writers above-mentioned that the "dip" in the splanchnic blood pressure curve is due to the pouring out of small quantities of adrenin causing a temporary depression during the course of a vaso-constrictor elevation of blood pressure The interesting discovery of MacDonald and Schlapp has rendered this hypothesis more secure We find that the "dip" does not occur in an animal entirely free of anæsthetic It is, then, a phenomenon dependent upon both adrenal secretion and the pharmaco-dynamical action of ether (and possibly other anæsthetics also) This has been confirmed in a large number of experiments upon pithed and decerebrate cats, and the uniform result has been that, when adrenin injected intravenously caused a vaso-dilatation, then and only then could we obtain the dip in the splanchnic curve

We hope shortly to publish further details

We are, Sir, yours faithfully,

SWALE VINCENT,
F R CURTIS

Physiological Department, Middlesex Hospital Medical School, Feb 8th, 1927

IMMUNITY TO IMPLANTED TUMOURS

To the Editor of THE LANCET

SIR,—Since my previous letter, Dr Lumsden has kindly shown me his slides There is now no doubt in my mind that he is dealing with carcinoma cells In my opinion, the reason why they do not exhibit the usual appearance of growing in continuous sheets of cells is because they are not "healthy" These are more or less degenerated as evidenced by fatty degeneration of their cytoplasm and the beginning of nuclear pyknosis Dr Lumsden maintains that such cells will continue to exhibit evidence of vitality (for instance, movement) for some weeks, but when exposed to certain antisera degeneration proceeds at a greatly increased speed In contrast to this "healthy" normal cells such as fibroblasts or kidney cells do not undergo this rapid degeneration Though it may be fair to compare degenerating carcinoma cells with each other, it seems doubtful whether this can be done with advantage when degenerating carcinoma cells are contrasted with healthy cells

I am, Sir, yours faithfully,

J C MOTTRAM.

The Radium Institute, Portland-place, London, W 1, Feb 2nd, 1927

To the Editor of THE LANCET

SIR,—In reply to Dr Drew's letter the migrating cells mentioned in my letter in your issue of Jan 29th as having given rise to cancer when inoculated into mice, were collected after removal of the fragment from which they emanated They were injected alone in a small quantity of serum The experiment is a delicate one, and it is obvious that the small number of cells inoculated after considerable interference should not be expected to cause a progressive tumour in every case In three out of ten mice so inoculated a progressive and typical M63 tumour was produced, and this to my mind is alone sufficient proof that these migrating cells are malignant I and others who have worked much with my medium and methods have no doubt at all on the point, and I think that only unfamiliarity with the results obtained could be the basis of the doubts existing in the minds of Dr Mottram and Dr Drew. A few further points confirmatory of my views may be worth setting down:—

1 Not infrequently both cancer cells and unmistakable stroma cells migrate out of a fragment of M63 Application of antihuman cancer serum kills every cancer cell and causes no damage to the stroma cells

2. When a tiny fragment consisting of, say, 30 or 40 cancer cells is watched under the microscope these cells can be observed to wander out, and have exactly the same characters as those migrating out of a larger fragment

3 Where fibroblasts from the heart or salivary gland or epithelium from the kidney are intermingled with these cancer cells, the latter only are killed by an antimalignant serum—e g, from a rat hyperimmunised to J R S See Figs 3 and 4, in my paper in THE LANCET, 1926, ii, p 112

4 Fragments of M63 grown in normal serum invariably cause cancer when inoculated into mice Fragments to which anti-M63 serum has been applied do not cause cancer

5 The results obtained in the treatment of tumours in the living animal are confirmatory of the views I maintain, and are the fruit thereof

I will gladly show Drs Mottram and Drew actual specimens which I hope may convince them, but their repeating my experiments is the only certain means of doing so In the belief that truth emerges more readily from experimental observation than from correspondence, I propose to continue the former and not the latter

I am, Sir, yours faithfully,

THOMAS LUMSDEN

Lister Institute of Preventive Medicine, London, S W, Feb 5th, 1927

PS —Since I wrote the above, with Miss A C Kohn-Speyer I showed some specimens to tissue culture-specialists and others at the meeting of the Biochemical Society on Feb 7th All were, I think, convinced of the malignant nature of the cells migrating from my cultures of mouse cancer I am glad to state that after examining the specimens Dr Mottram, with a candour worthy of his reputation, admitted the malignant nature of these cells, although I think he was not so convinced as, by long experience, I am, of their activity and power of resistance Dr Drew, though invited, was unable to be present In vitro tests give useful indications, but the conditions are necessarily abnormal and only results obtained in living animals are entirely convincing to my mind My method consists in killing these cultured

CONTINENTAL MEDICAL TOURS —The *Bruxelles Médical* has arranged a number of tours to Morocco and to the Eastern Mediterranean, in which doctors and their families are invited to take part at reduced rates The dates of starting are from March 12th onwards, and full particulars may be had from the Section des Voyages de *Bruxelles Médical*, 29 Boulevard Adolphe Max, Brussels

CAMBRIDGE GRADUATES' MEDICAL CLUB —The annual dinner of the Club will be held at the Langham Hotel on Tuesday, March 1st, at 7 15 for 7 30 P M Sir Humphry Rolleston President of the Club, will take the chair All members of the Club are invited to be present, and all Cambridge medical men who are graduates of the University are eligible for membership Application forms can be obtained from the honorary secretaries, Mr R M Vick, of 113, Harley-street, London, W 1, and Dr F G Chandler, of 1, Park-square-west, Portland-place, N W 1

TERRITORIAL ARMY MEDICAL OFFICERS' ASSOCIATION —The annual dinner of the Association will be held on Thursday, Feb 24th, at 7 30 for 8 P M , in the Cafe Royal 68, Regent-street London W 1 The Association has been formed for consideration of all matters of interest or benefit to the Territorial medical officer The dinner tickets are 12*s* 6*d* (without wine) and can be obtained from the hon secretary, Lieut -Colonel L A Harwood, at 37, Russell-square, London, W C 1

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH —A quarterly meeting of the College was held on Feb 1st, Prof G M Robertson, the President, in the chair Dr James Richan Drever and Dr Alan Leonard Smith Tuke were introduced and took their seats as Fellows of the College Dr William Bell was elected a Fellow of the College, and the following were elected Members . Robert Finlay Aitken, Sittampalam Thiagarajah, Alexander Murray Affleck, James Kirkwood Slater, and Prag Nath Kapur

HOSPITAL SATURDAY AND SUNDAY FUNDS —The delegates of the London Hospital Saturday Fund have just distributed £69,000, a reduction of about £2400 on last year The falling off is accounted for by the industrial depression The general hospitals, 47 in number, received £22,790, and 79 special hospitals £21,808 Altogether 235 institutions benefited —The same influences account for a falling off of nearly £1000 in the produce of Birmingham Hospital Sunday Fund, which is more than accounted for by smaller church collections , the total was £8782 The administrative expenses have fallen from 9 6 in 1923 to 6 2 in 1926

AN OVERCROWDED UNION INFIRMARY —Dr J. D. Giles, the medical superintendent, has reported to the Salford Board of Guardians upon the overcrowding of Hope Union Infirmary In addition to the congestion of the wards, a large proportion of the day-rooms have had to be used for sleeping accommodation for sick patients, while others have been sleeping on floors and tables in almost every ward There are 1014 patients in a hospital which was built to accommodate 850 A committee has been appointed to deal with the matter

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Thursday, Feb 17th, at 5 P M , at the rooms of the Medical Society of London, 11, Chandos-street, W 1, Dr Wilfred Harris will lecture on Trigeminal Neuralgia On Feb 14th, at 2 P M., Mr Harold Kisch will hold a demonstration in clinical surgery at the Central London Throat, Nose and Ear Hospital those intending to be present are asked to notify the hospital secretary (Museum 1539) On Feb 18th, at 5 P M , Mr G Viner will give a clinical demonstration on Ocular Palsies at the Royal Westminster Hospital The lecture and both demonstrations will be open to members of the medical profession without fee The following courses are in progress this month at the Lock Hospital, in Venereal Diseases , at the Paddington Green and Victoria Hospitals, in Children's Diseases , at St John's Hospital, in Dermatology , and at the National Hospital, Queen-square, in Neurology Details of any of these courses can be obtained from the Fellowship The subjects of the Special Courses in March will include Diseases of the Chest, Brompton Hospital, all day for one week, fee £3 3*s* Diseases of Children, Queen's Hospital, all day for two weeks fee £3 3*s* , Ophthalmology, Royal Eye Hospital, afternoons for two weeks, fee £1 1*s* , Gynæcology, Chelsea Hospital, mornings and/or afternoons for two weeks, fee £5 5*s* and Orthopædics, Royal National Orthopædic Hospital, all day for two weeks, fee £2 2*s* There will also be a practitioner's course at the London Temperance Hospital in the late afternoons for two weeks (fee £1 1*s*) Practical courses in Anæsthetics can be arranged, and also courses in Obstetrics , arrangements are made for clinical assistants Syllabuses of the Special and General Courses and copies of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1.

MANCHESTER CITY COUNCIL AND VACCINATION —The city council at its meeting on Feb 2nd, by 73 votes to 31, supported a resolution of its public health committee, urging upon the Ministry of Health the importance of amending the Vaccination Acts so as to make vaccination "more general and efficient " The resolution supported the resolution passed by a conference of medical officers of health in Durham urging the Ministry to amend these Acts and to make vaccination more general and efficient as vaccination afforded "the quickest, most scientific, and most economic means of preventing and arresting outbreaks of small-pox "

BIRMINGHAM MATERNITY HOSPITAL —Little more than a year ago there was opened debt-free a new block of this hospital which increased the number of beds from 32 to 67 and provided much collateral accommodation The old building was then overhauled and a new operating theatre and a pathological laboratory were built The result of these necessary enterprises is a heavy deficit The hospital is an institution of primary importance to Birmingham It treats in-patients (1237 last year) and out-patients (2446 last year) provides qualified resident midwives in seven districts of the city who attend patients in their own homes, and is a training school for midwives and the medical students of the University

JOINT TUBERCULOSIS COUNCIL —At a meeting of the Council held at 1, Upper Montague-street, London, W C , on Jan 15th Sir Henry Gauvain was elected chairman for 1927 Dr Lissant Cox vice-chairman, Dr E Ward, Secretary, and Dr James Watt, Treasurer A committee was appointed "to consider how the tuberculosis service may be rendered more efficient , whether, with this object, evidence shall be given before the Royal Commission on Local Government , and, if so, what points should be brought forward " Fourteen years' experience of the working of tuberculosis schemes has brought some knowledge of their possibilities as well as their limitations, and the committee represents all the interests concerned Recent statistical returns for which the Ministry of Health has asked are likely to lead to modifications in administration, and the time seemed appropriate for tuberculosis workers to overhaul their methods On behalf of the Research Committee Dr S R Gloyne presented a report on Disinfection Dr Lissant Cox reported that replies were coming in to the 3800 circulars issued on "The Fate of Children in Tuberculous Households" Dr W Brand outlined the post-graduate courses proposed for the present year one at Copenhagen, one in London on non-pulmonary tuberculosis, at which light treatment would be dealt with, besides artificial pneumothorax, the interpretation of X ray plates, and other modern aids to diagnosis and treatment The Council meets next on Saturday, May 21st, at 10 A M

UNIVERSITY OF LONDON —The title of Professor of Psychology has been conferred on Miss Beatrice Edgell, Ph D, D Litt, in respect of the post held by her at Bedford College

AN INTERNATIONAL CONGRESS AT FRANZENSBAD —Medical men attending the Second International Congress in Female and Cardiac Diseases which will be held at Františkovy lazné (Franzensbad) in May, will be granted a free Czechoslovak visa Further particulars may be had on application to the Czechoslovak Legation, 8, Grosvenor-place, London, S W 1

ROYAL SOCIETY OF ARTS —On Wednesday, Feb 23rd, at 8 P M., Mr Francis H Carr, President of the Society of Chemical Industry, will lecture on Insulin and its Manufacture

CONVALESCENT HOME FOR GLOUCESTER —A lady living near Gloucester has given her house and an endowment of £1000 a year for a convalescent home for women and children of Gloucester The home will be opened in May for 20 inmates

CHELSEA CLINICAL SOCIETY —A meeting of this society will be held at the Rembrandt Hotel, Thurloe place London, S W, on Tuesday, Feb 15th, at 8 30 P M, preceded by dinner at 7 30 P M. There will be a discussion on the Acute Abdomen, the speakers including Sir John Broadbent, Mr Duncan Fitzwilliams, and Mr Zachary Cope

INTERNATIONAL POST-GRADUATE MEDICAL COURSE.—A number of courses are to be held at Berlin under the auspices of the University and other bodies The subjects include Progress of Medicine (March 1st to 12th), Diseases of the Heart, Kidneys, and Vessels (March 14th to 23rd); Scientific Knowledge of Rays (March 24th to 31st), and Diagnostic and Therapeutic Technique (April 1st to 14th) There will also be other special courses and opportunities for work in Berlin hospitals Further particulars may be had from Kaiserin Friedrich-Haus Berlin N W 6, Luisenplatz 2–4

SPAHLINGER TREATMENT OF TUBERCULOSIS —The following resolutions have been passed at a meeting of the Lancashire and Cheshire Branch Council of the British Medical Association —

(1) That the branch council reaffirms the decision of March 24th, 1926, that a case has been made out for a full investigation of the Spahlinger treatment in England under complete medical supervision

(2) That under no circumstances does this branch of the B M A lend its name or reputation to the support of a public appeal for funds in relation to the Spahlinger treatment until such investigation has taken place in England with a successful issue

POST-GRADUATE TOUR IN THE UNITED STATES OF AMERICA AND CANADA —A tour is being organised by the Section of Surgery of the Royal Society of Medicine to start on July 23rd, 1927 It is proposed that the complete tour shall take about six weeks Among the places visited will be Boston, New Haven, New York, Philadelphia, Baltimore, Washington, Cleveland, Detroit, Ann Arbor, Grand Rapids, Chicago, Rochester (Mayo Clinic), Great Lakes, Niagara, Toronto, Ottawa, and Montreal Facilities will be offered to members who wish to shorten the tour, which is primarily organised for surgeons, but arrangements will also be made for those interested in other branches of medicine The cost of the whole tour inclusive of ocean passage, rail and other transport, hotels and meals, will be approximately £140 Travelling facilities on the same terms will be offered to the wives of those taking part in the tour Further particulars may be obtained from Mr C Max Page, 134, Harley-street, London, W 1

MIDDLESEX HOSPITAL NEW INSTITUTE OF OTO-LARYNGOLOGY —On Feb 8th the new Institute of Oto-laryngology, presented to the Middlesex Hospital by Mr T R Ferens, was formally handed over by him to Prince Arthur of Connaught, chairman of the hospital At present housed in the annexe, the institute will be transferred to new quarters as soon as the rebuilding of the hospital is complete It consists of a general library, three research laboratories, a common-room, a library and museum, a photographic dark room and a lecture-room Mr Ferens's gift was the sum of £20,000, and as the institute is to be used exclusively for research and teaching, it is hoped that studentships may be provided for post-graduates Eight or ten of these workers can be accommodated and no charge will be made for the use of apparatus and equipment. Such students, however, will have to find their own maintenance and, in order that candidates of exceptional merit may be enabled to take up research work at the institute whether they can support themselves or not it is proposed that three post-graduate studentships of £300 each should be established, for students from the United States the Dominions, and Great Britain respectively The admirable equipment, and the fact that the institute is to be devoted to research will, it is hoped, make it a centre of post-graduate instruction in oto-laryngology to which students will come from all parts of the world, and it is intended that the studentships shall be reserved for graduates of special ability After Prince Arthur of Connaught had formally received the institute from Mr Ferens, the value of the gift was acknowledged by Mr Somerville Hastings, aural surgeon to the Middlesex Hospital, and Mr F J Cleminson, assistant aural surgeon At the conclusion of the proceedings Prince Arthur announced that Mr Bernhard Baron had offered to endow the British studentship at the institute

Leeds City Tuberculosis Sanatorium Killingbeck —Asst. Res M O £250
Liverpool Open-air Hospital for Children Leasowe —Jun M O £200

The Chief Inspector of Factories, Home Office London S W, announces a vacant appointment for a Certifying Factory Surgeon at Clwt y Bont, Caernarvonshire

Births, Marriages, and Deaths.

BIRTHS

BROOKS —On Jan 29th at Louise Margaret Hospital, Aldershot the wife of Captain J E Brooks, R.A.M C of a son

DANSIE.—On Feb 6th, to Dr and Mrs Dansie, of Welwyn—a son

HAMBER —On Feb 3rd at Lowlands, Fordingbridge, Hants, the wife of John F Hamber M.R.C S, M.R.C P of a son.

STEPHENS —On Feb 2nd, at Withington Hall Withington, the wife of Dr James R W Stephens, of a daughter

WATNEY —On Feb 3rd at Heron Croft, Woldingham the wife of Dr. Martyn Watney, of a son.

WINDER.—On Feb 6th, at a nursing home, Southampton the wife of Lieut -Colonel M G Winder R.A.M C, of a daughter

MARRIAGES

BRADNACK—KIRK —On Feb, 3rd 1927, at St Andrew's, Newcastle-on-Tyne *Gerald A A Bradnack*, M.R.C S L.R.C P, of Barton-on-Humber, Lincs to Nora Winifred Kirk M B, B.S Durh, of 34 Eldon place, Newcastle-on-Tyne

NORCOTT—COOK.—On Feb 3rd, at Wesleyan Church Wallington William Boyle Norcott, M.R.C S Eng., L R C P Lond., to Margaret youngest daughter of the late Mr and Mrs W T *Cook, Cranley House* Wallington.

PATEY—SUMMERS —On Feb 5th at Holy Trinity Church Hounslow, David Howard Patey, F R.C.S to Gladys Joyce daughter of Mr G Hamilton Summers, L D S and Mrs Summers, of Hounslow, Middlesex.

DEATHS.

ARNOLD —On Feb 5th at Byfield House Painswick Gloucestershire after a few days' illness, Francis Sorell Arnold B.A., M B Oxf in his 67th year

CAIE.—On Feb 6th at Cobden road Edinburgh William James Caie M.A., M.B Ch B, of Highbury House, Bury St. Edmunds

ELLIOT —On Jan 30th at Greenhill-gardens, Edinburgh after a very short illness Andrew James Elliot, M.D F R.C S E of Ardfenaig Isle of Mull, and formerly of Noakachari Assam

HEDLEY —On Feb 4th in London, suddenly, of heart failure John Hedley, J P, M D of Cleveland Lodge, Middlesbrough aged 84

HOGGAN —On Feb 5th at a nursing home in Brighton Frances Elizabeth Hoggan, M D in her 83rd year

SMITH —On Feb 5th at Redcroft Port Talbot D Lloyd Smith, M B Lond, of Llandrindod Wells, aged 55

STEDMAN —On Feb 2nd at Bramcote Weybridge Frederic Osmund Stedman M D aged 64 years

TRIGGS —On Feb 1st at a nursing home at Malden Surrey Fleet Surgeon J B Bowden Triggs M B R N formerly of Southsea in his 76th year

N B — A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

ABRAHAM CHOVET.

Dr William Snow Miller, of Madison Wisconsin, contributes to Annals of Medical History vol viii No 4, an interesting paper upon a little known but outstanding figure in American medicine—namely, Dr Abraham Chovet, who was one of those eccentric personalities in which the eighteenth century was so rich Little is known of his early life, but his father, David Chovet, was a wine merchant in London, and Abraham was born in 1704 and was probably French by extraction In 1720 he was apprenticed for seven years to a surgeon by name Peter Gougoux Lamarque, a foreign brother of the Barber Surgeons Company, at a fee of 100 guineas When out of his articles he went abroad and studied anatomy under Jacques Benigne Winslow in Paris In 1732 we find him returned to London, giving lectures and demonstrations in anatomy, and publishing a small brochure of 26 pages, about 6 by 8 inches, with the inclusive title "A Syllabus or Index of all the Parts that enter the Composition of the Human Body; in Twelve Lectures for the use of those that go through Courses of Anatomy." Chovet had been in the habit of using wax figures of anatomical preparations which made by Denoue, professor of anatomy to the Academy of Sciences at Paris had been brought to London. These apparently did not satisfy Chovet for he mentions in the preface to his syllabus that he had "contrived a body in wax (now in hand) wherein the action of the heart and lungs and the circulation of the blood, will be made visible which I hope in some time to complete." By 1733 this aim was attained, for an advertisement in the *London Post* on Dec 27th of that year states that there is to be seen "this day and for the future, at Mr Lamark's, Surgeon in Orange-street, Leicester Fields, Mr Chovet's, the Surgeon's New Figure of Anatomy, which represents a woman chained down upon a table, supposed opened alive wherein the circulation of the blood is made visible though glass veins and arteries the circulation is also seen from the mother to the child . . . . with the Histolick (*sic*) and Diastolic motion of the heart . ." In 1734 Chovet was appointed a demonstrator to the Barber Surgeons, but continued to give "Compleat Private Courses of Human Anatomy," particulars of which could be obtained at various places and amongst others at the Rev. Dr. Desaguliers's house in Channel-row, Westminster This Desaguliers was most likely John Theophilus, a natural philosopher of Huguenot extraction, born at Rochelle, lecturer on experimental philosophy at Hart Hall, Oxford, in 1710, rector of Whitechurch, Middlesex, in 1714. He died in 1744. In 1736 Chovet resigned his position as demonstrator and left London; according to a story related by Weir Mitchell, whose father had it from Dr Physick, 1768-1837, Chovet had tried to save a malefactor about to be hanged by doing a preliminary tracheotomy, and the Government of the day did not regard this experiment with favour History does not record whether the attempt was successful but Chovet left the country. After a somewhat erratic sojourn in the West Indies he settled about 1774 in Philadelphia, taking a house in Vidal's-alley, where he at once commenced a course of lectures on anatomy, delivered "on elegant Anatomical Wax Figures" The opening lecture, delivered on Nov 25th was according to the contemporary press notice in the *Pennsylvania Gazette* "conducted with the greatest politeness and decorum, and the company departed expressing themselves in the highest terms of approbation." The elegant anatomical wax figures passed after Chovet's death into the keeping of the Pennsylvania Hospital and afterward into that of the University. Their ultimate fate is not exactly known, but in all probability they perished in the fire which destroyed much of the University museum in 1888 Alongside of his work in anatomy, Chovet would seem to have enjoyed a thriving clinical practice in spite of, or possibly on account of, his many eccentric habits He died in March, 1790, in his eighty-sixth year.

INFLUENZA IN 1782.

INFLUENZA is much discussed on all hands *just now*, and it would be singular if it were not The public interest is proved by the many articles—most of them written upon real information—which are appearing daily in the press. Our descendants should find the writing of medical history much facilitated The influenza epidemic of 1782 is alluded to in all histories of the disease but how uncertain is our information It seems to have been attended with more than ordinarily violent symptoms and has been recorded by a number of witnesses who had not, however, the assistance of a popular press Of these one of the most explicit was Dr R *Hamilton* of Luton whose "Description of the Influenza" was published in 1782 In May of that year the public had been debilitated by months of cold wet weather On the 22nd the thermometer stood one degree

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W

THURSDAY, Feb 17th —8 15 P M , Lieut -Colonel W P MacArthur · Old-Time Typhus in Britain, preceded by a demonstration on the subject at 7 45 P M

Hunterian Oration

ON

HUNTER'S IDEALS AND LISTER'S PRACTICE

Delivered at the Royal College of Surgeons of England on Feb. 14th, 1927,

By Sir BERKELEY MOYNIHAN, Bart
K C M G., C B , M S Lond ,
PRESIDENT OF THE COLLEGE

On this day, the 199th anniversary of his birth, we commemorate the services of John Hunter to the Science and the Art of Surgery In this year we celebrate the centenary of the birth of Lister Hunter and Lister! From all who have ever served the cause of surgery these two stand apart by reason of the immeasurable gifts which they have conferred upon their fellow men May we now recall something of Hunter's work and of his ideals in respect of the conquest of disease which the genius of Lister made possible?

Man's life is warfare The individual, the whole race, is beset by foes, unresting, relentless Against them our defence, if we are ever to subdue them, must be carefully planned and diligently strengthened But defence, however stubborn, is not enough Attacks designed after scientific study of the enemy strongholds and methods, and launched with impassioned zeal, must never for one instant falter Not all our attacks meet with success We are cheered when we gain some notable victory, yet when we suffer defeat, as wave after wave of our advance is checked and repulsed, we do not lose heart Failure inspires us to fresh and still more eager endeavour

In this year, the centenary of Lister, we rejoice to acclaim the greatest victory ever won by man against his enemies We, who are in active work to-day, are perhaps unable to measure the full extent of that victory, for during the long fight, lasting almost exactly 60 years, our standards have been so changed that we cannot truthfully compare our work with that of our intellectual ancestors Operations from time immemorial so mortal as to be prohibitive, are now freely performed without anxiety Operations formerly unimaginable are now matters of everyday occurrence The mere tale of such work done does not adequately illustrate the change On my last day as surgeon, on the full staff of my hospital, I performed six abdominal operations *Not one of* these was practised by any member of our staff during *the year in which I became* house surgeon, nor had such a diagnosis as was made in three of these cases, and verified at the time of operation, ever then been attempted in the history of *medicine* *Above all*, a statement of facts and a comparison of methods does not in adequate degree convey to our minds the difference of outlook of the intellectual and *spiritual* approach of a man to his daily task, as between the surgeon in the days before Lister and since It is barely possible for us to imagine how men felt about their daily work when an eminent surgeon could speak of his hospital as a "house of death", when hospitals "were little short of pest houses," as Lister said,[1] and when the oppressive mortality compelled the closure of wards or of a whole hospital for months, until the curse was lifted from them

BEFORE AND AFTER LISTER

The change, *of incalculable* benefit to humanity, is due to *one man, Lister*[2] Before Lister's time the surgeon dreaded the almost inevitable consequences of his operation Lister made surgery so free from risk that we now may say that, with due care in the detailed application of the lessons learnt from him, it is no longer the fatality of the operation itself which is feared In these days when a patient dies it is not because the operation leads to septic complications which he cannot withstand We fear for him chiefly, if not only, when the extent of the operation is formidable, or when the most sensitive regions of the body, sometimes remote and almost inaccessible, are attacked by methods which half a century ago were beyond the wildest dreams of the most adventurous mind Our main concern in these days is with the condition of the patient before and after operation. We seek to make him as safe for surgery as surgery has been made safe for him Lister, in short, has made all the methods applied by the surgeon almost devoid of risk in *themselves* The risks run are dependen upon accessory factors, upon the state of the patient the nature and extent of the disease, the intrinsic susceptibility of organs, or the anatomical conditions responsible for the difficulties which must be surmounted

Do we fully realise the implication of all these statements? We are at the end of an epoch, indisputably the greatest in our history, the epoch in which manipulations by the surgeon have been robbed of the prohibitive dangers which formerly repelled Now when failure comes it is the individual who fails, not the methods of which Lister laid the eternal and unshakable foundations Lister by his genius recruited an army of surgeons which has gained astounding victories The human body from crown to toe has for all time become our indisputable kingdom, within which we may come and go at pleasure, undismayed by the pestilencies which menaced us before Lister forever subjugated our enemies Lister is indeed Captain of the men of life.

We, who inherit the glorious legacy of Lister, must not be content merely to enjoy and exploit our incomparable heritage No great teacher measures his success in contemplation of his own efforts His greatness lies rather in the work which he inspires others to do, in the tradition not of past accomplishment, but of future *devotion* Traditions are fostered and increased, not by routine observance of ancient ceremony nor by mute obedience to outworn creed, but by active faith forever seeking new truths and exploring new paths, in conformity with the old spirit and with unchanging devotion to the great ideal of which the tradition is the shrine There is immortality of the tomb, and immortality of the resurrection The soul of a great teacher is born again in his pupils We are Lister's disciples What, then, are we to do with his gift to mankind? We use it already to the immense advantage of the individual sufferer, a therapeutic weapon of unapproached perfection, we are making it, and we must continue in increasing degree to make it, far *more than that* After the Great War the statesmen of Europe, moved by the highest ideals, sought, not perhaps wholly in vain, to convert the allied victory into lasting peace The statesman's ideal is a warless world War is to end war Ideals are not so much for capture as for pursuit, and though the statesman may never attain his ideal, yet the happiness and progress of mankind surely depend upon the grim and perhaps endless struggle to reach it. So, too, for us surgery must be regarded as the most powerful weapon of research upon man and animals ever given to our hands, and the end of research is not the cure only, but far better the prevention, of disease

JOHN HUNTER'S CONCEPTION OF SURGERY

The oration I have now the honour to deliver was founded 114 years ago as "a lasting mark of respect to the late John Hunter"[3] Let us turn to Hunter, the greatest surgeon of all the ages before Lister, and see how he regarded the art he practised In the opening lecture of each surgical course, Hunter said to his students,[4] "The last part of surgery, namely operations, is a reflection on the healing art; it is a tacit acknowledgment of the insufficiency of surgery It is like an armed savage who attempts to get that by force which a civilised man would get by stratagem." In his "Treatise on the Venereal lower than on the preceding Dec 22nd, and Whitsunday was as cold as Christmas Day Hamilton describes a terrific May thunderstorm, and this reminds us that the old writers generally regarded influenza epidemics as dependent on sensational changes of weather or connected with volcanic eruptions The influences of the stars and the heavens had, indeed, been long held to preside over disease, especially over sudden epidemics The Italian name influenza signified astral influence and was first generally used during the great epidemic in 1743

Standing in the street of Luton, Hamilton watched the lightning, which appeared not in flashes, " but in large balls, one rolling after another over the heavens northward, and now and then dashing one against another " This was an omen, for nearly at the same time the influenza appeared suddenly in London, and spread with such rapidity that one city physician visited 107 patients in one day The symptoms were peculiar in their severity—a great cough, violent sneezing, and coryza, the latter " excoriating the upper lip and vellicating the membrana sneideriana, rendering the inside of the nose extremely painful " A soreness over the eyes was complained of " chiefly about the brows, which they [the patients] said was seated in the bone, and rendered them stiff and painful to be opened " and susceptible to light There were the usual diffused pains all over the body, but not much temperature, which in those days had to be judged from cutaneous sensation, with deductions from the pulse-rate A traveller leaving London early in the morning observed " many of those who cry things for sale, to lean their heads against the walls of the houses, and cry their goods , not being able to support themselves upright " Coalmen and certain costers are still seen to put a hand to the side of the face when uttering their bellow This may be a ritual reminder of the old epidemics when people leant their heads against walls before shouting, or it may be done to deaden the noise to the shouter, or, again, it may be intended to direct a shout

The influenza was still somewhat of a novelty in 1782 In one of Samuel Foote's comedies of date 1770 it is referred to as " the new influenza," though in 1762 Mrs Montagu refers to it as the " fashionable cold " The 1782 influenza was one of 11 severe epidemics which raged in England from 1693–1790 In the nineteenth century there were six great epidemics up to 1874, but the greatest series occurred in 1789–92, when the death-rate in London was alarming In 1782 Hamilton notes that few died, though all patients suffered from intense weakness The Parisians laughed at the unpleasant scourge at that time, nicknaming it the " petit poste " and " petit courier "

SHREDDED SUET AND GROUND RICE

AT Stoke-on-Trent on Jan 28th, before the Potteries Stipendiary Magistrate, an important test-case was heard, when two grocers were summoned for selling shredded beef suet adulterated with ground rice The prosecution stated that the shredded suet was made in Manchester and samples purchased at one of the shops had been found to contain 21 9 per cent of ground rice, and those bought at the other 19 8 per cent It was submitted that a proper standard was 15 per cent For the defendants it was claimed that about 19 per cent was a fair standard The magistrate, who reserved his decision, said there was no question of fraud of deceiving the customer, or of concealing inferior ingredients It was purely a question of what was an excessive quantity of rice, a certain amount being necessary to separate the suet

GENIUS AND DISEASE

THE publisher's note to Dr A C Jacobson's[1] attempt to appraise for popular information the influence of disease upon artistic performance, is that we have here " a sane and balanced close-up of the men of genius, whose lives and work have been affected by drugs, drink, and disease " The little book may be a " close-up "—we do not take the publisher's analogy but it is not sane, for the deductions are not based in a healthy way upon logical evidence , and it is not balanced, for the quality (whatever it may be) that is implied by the term " genius " is credited in no proper proportion to the victims of the " close-up " The author's thesis appears to be that men of genius require disease, drugs, or alcohol to set free the creative powers which are resident in their secondary personalities , and as witnesses to the power of alcohol he cites 76 names Are we to agree that all these are people of genius on any balanced view ? And is it a sane conclusion from the enumeration that Æschylus, Caracci (which ?), Handel, Kingsley (which ?), Stephen Collins Foster, and Richard Le Gallienne owe their respective fames—and these are hardly of comparable quality—to the use of alcohol ? Are we to believe, because Horace praised Falernian wine, and Brouwer depicted revelling boors, and Sheridan urged the company to " let the toast pass," and certain of Dickens's immortal creations indulged in convivial drinking, that these undoubted men of genius consumed alcohol in any unusual manner, or did their best work only under its influence ? Did Omar pass his off-time sitting under a tree with a jug ? If Dr Jacobson should reply that no such questions arise fairly out of his book, he has failed in the trade of an author by not making clear what he is writing about The same reflection is induced by perusal of subsequent chapters Dr Jacobson cannot have had time to acquire personal acquaintance with the work of those whose names he cites with complacent profusion—no one could possess such encyclopædic knowledge Nor has he found time to inquire into the validity or significance of the biographical details relied upon for the distribution of sinister stigmata The publisher acclaims the work as " scientific in its content," but a less scientific approach to an important subject could hardly be imagi

A DEFINITION OF DRUNKENNESS IN THE NAVY.

WE learn from the current issue of the *Journal of the Naval Medical Service* the proper meaning to be attributed to the word " drunk " in naval practice The Admiralty has laid down that a charge of drunkenness to be supported by evidence " that, through the intoxicating effect of liquor, the accused was unfit to be entrusted with his duty " The responsibility of the primary decision rests with the accused's commanding officer, but if there is any doubt about the reason the medical officer's opinion should be obtained at once, lest, a plea of sickness being brought forward at the court-martial, a guilty person may escape due punishment The medical officer, if called in, may be required to give his opinion of the accused's fitness for duty, and must determine whether his condition can be accounted for wholly or in part by disease or injury Therefore he should perform a complete and comprehensive examination at once, whether the accused complains of any disability or not He should take complete notes at the time and try to form, from observed facts, an opinion whether accused's condition and behaviour are normal or abnormal, and whether he is fit to do duty ; if his conduct and behaviour are abnormal, whether this is due to consumption of alcohol or to disease or injury and in what proportions These opinions will be stated in the medical officer's summary of evidence, if a court martial should follow

A NEW EDITION OF LEE'S " MICROTOMIST'S VADE-MECUM "

To the Editor of THE LANCET

SIR,—In conjunction with Dr E V Cowdry, of the Rockefeller Institute, N Y , I am editing the ninth edition of this book which it is proposed to bring out shortly In addition to general technique the book will contain articles by experts on neurological technique, protozoa, histological applications of measurements of acidity and oxidation, microdissection, cultivation of tissues in vitro, fats, bone and teeth, and cytological technique The purpose of this letter is to invite research workers and others to forward to me, as soon as possible, any new information which they may be glad to have incorporated in the book It is not proposed to include bacteriological technique

I am, Sir, yours faithfully,

J BRONTE GATENBY

Zoological Department, Trinity College, Dublin,
Feb 4th, 1927

OVERFEEDING IN PREPARATORY SCHOOLS

To the Editor of THE LANCET

SIR,—I have had a letter from a correspondent who asks " Can anything be done about the overfeeding, and especially over-starchy feeding, in first-class preparatory schools ? I went lately to see a small cousin at such a school There the boys have six meals a day, the three intermediate meals consisting of milk and biscuits, rock cakes, bread and butter, and buns The headmaster's wife assured me that ' the boys have no time to be hungry ' This school can be no exception, for when we ask a young nephew at another what he has to eat his reply is punctuated at intervals with ' And then we have cocoa and biscuits ' Fruit, with the exception of bananas, appears to be rare The diet mentioned at the first school was, of course, in addition to ' tuck ' three times a week A good many of the errors come, I believe, from ignorance and not from pig-headedness "

These observations accord generally with my own, which are the result of frequent contact with schools of all kinds My committee will be glad to advise heads and housekeepers of schools on suitable dietaries

I am, Sir, yours faithfully

CHARLES E HECHT,

Hon Sec , Schools Committee, Food Education Society

Tufton street, S W , Feb 4th, 1927

[1] Genius Some Revaluations By Arthur C Jacobson New York Greenberg and Co 1927 $2 50

the activity and the growth of surgery depend upon the nourishment which biology may bring. Unless surgery calls in the aid of all the sciences with which biology is related it will remain as static as ancient geometry, whose figures were drawn once for all. Modern geometry is concerned with function, with the variations of movement by which a figure is described. Surgery's concern in the future will not only be with the states produced, with established organic disease, but with its allies it will help to eradicate some of those variations in function by which perhaps they have been caused, with which they are associated, and by which their presence is declared.

If sometimes we blame Sharpey and his school for the unhappy cleavage between anatomy and physiology,[6] we must at least acknowledge the great debt we owe to him for laying so firm the foundation of new methods for the studying of functional anatomy in man and in animals Physiology, with its offspring biochemistry, has introduced physical and physico-chemical methods ;-methods of quantitative observation which have supplemented where they have not supplanted the merely qualitative methods. The brilliant work of Sherrington Lucas and others upon the nervous system gave us fresh conceptions of it; further advances along their lines were becoming difficult until the application of thermionic valves made it possible, by recording the transmission of impulses in the afferent nerves, to investigate the effects of stimuli upon the sensory end-organs And in the interpretation of symptoms a study to which my old friend James Mackenzie bent the strength of a most eager and original mind physiology alone can read the occult significance In acute pancreatitis there is, as Halsted,[7] a great benefactor of mankind, first told us, a lividity of the face. Why? Is it due to some disordered action of the respiratory system imposed by the closeness of the affected organ to the diaphragm and the structures which lie above it or is there circulatory stasis, or alteration in the blood pigment?

Physiology is the master of all the methods by which these three possible causes may be quantitatively investigated. Estimations of the oxygen saturation of the arterial blood give information of disturbance of respiratory function: information which we may compare to that derived from a measurement of the amount of blood-urea when the renal functions are deficient Estimations of the carbon dioxide combining power of the blood are essential if we are to recognise the presence and the degree of acidosis Circulatory stasis may be gauged by the ethyl iodide method of measuring the circulation rate. Alterations of the blood pigment are detected by the spectroscope and quantitative estimations of abnormal pigments are readily made after the method of Hartridge.

Like the physiologist the bacteriologist is engaged in work which is ranged alongside our own. The more he discovers of the offensive powers of bacteria and of the defensive mechanism of living flesh under their attack, the nearer are we brought to our surgical ideal The alliance between bacteriologist and surgeon has been necessary for the proof that the true estimate of an antiseptic is not measured only by its bactericidal value tested in the laboratory, but also by its power to encourage the blood serum or the tissues themselves to ward off and to break up an attack. Hunter, with the crude methods which were all he had at his disposal, demonstrated the tryptic power of wound discharges and anticipated a part of the admirable work of Almroth Wright during the war. Who could have imagined, when Lister's work began, that to-day we should be able to keep tissues alive in our laboratories, breeding them and growing them in captivity, separating the one kind from the other, noting the influence which one type of cell is able to produce on its neighbours and thus coming by the kind of knowledge which John Hunter so earnestly sought, a knowledge of the intrinsic processes of growth and repair? The problem of malignancy is now installed in our laboratories, and the cancer cell is being compelled to yield most reluctantly some of the complex secrets of its bolshevist behaviour.

The old art of vital staining, which Hunter learnt from Belchier, of Guy's, has taken on new improvements: by means of suitable dyes we can now select special elements in the living body, trace their movements and note their conduct The experimental embryologist, too, can help us if we seek to know in what manner the various tissues of the body come into existence.

These, then, are the allies of surgery in the Great War: biology in all its branches, chemistry, physics, radiology Never before has the master surgeon had such bountiful resources at his disposal. He cannot afford to neglect a single one of them. The urgent problem of our time is therefore a dual one We must seek to determine the line of advance which surgery will trace in the years ahead, increasing and strengthening our alliances; and we must earnestly discover how the leaders of our army of advance are to be trained. Are the old methods which in their day served so well still enough, or is the form of warfare already so changed, and now so rapidly changing, that a new discipline and a wider knowledge are needed?

HUNTER AND LISTER

To answer these questions we must look backward, and, calling upon our past experience, seek in the records of our great masters not so much what their knowledge was, but what methods they pursued as they qualified themselves for great leadership. We shall find at once that Hunter and Lister, incomparable among surgeons, each put himself through a long and arduous training never resting in his inquiries as to the activities of living matter, as to its behaviour in health, and its reactions in disease. At the threshold of our survey we recognise that the activities of our two leaders are not unrelated. Hunter's professional life covered the latter half of the eighteenth century, Lister's the corresponding half of the nineteenth century; between them there intervened two generations of surgeons My distinguished predecessor, the late Sir Rickman Godlee, who gave this oration in 1913, tells us in the life of his uncle Lord Lister[8] that "Hunter was Lister's greatest hero," that "his copy of Palmer's life of Hunter was marked in many places by pencil notes which show that he was studying it at least as early as 1855," that ' a proof of Sharp's engraving of the portrait of Hunter by Reynolds, which had belonged to Syme, hung in his study, ' that "he always spoke of Hunter with reverence Further, if we turn to the paper[9] which Lister read to the Medico-Chirurgical Society of Edinburgh in March 1858, on the "Causes of the Coagulation of the Blood" we find evidence of his early admiration of Hunter. ' The nearest approach," he wrote, "which I have been able to find to such an observation (that blood which is retained in the smaller veins of the body remains uncoagulated) is contained in that inexhaustible treasury of original observations and profound reflection, the works of John Hunter.

If I may borrow a simile from the football field to express the relation of these two great men I would say that it was Pasteur who made the final pass to Lister possible, it was Hunter's captaincy in the scrum that placed Lister in the scoring position. Indeed, we have to admit that while Hunter's resource in midfield has never been excelled, or even approached, and though the ingenuity with which he worked the surgical ball towards the goal remains unsurpassed, yet when he was in a scoring position and we are counting so confidently upon a "try," the ball is fumbled, and our hopes are foiled. The young surgeon of to-day can learn almost as much from Hunter's mistakes as from his triumphs

The Career of Work of John Hunter

Let us now examine the discipline to which John Hunter submitted himself to attain his leadership. He is the "Dick Whittington of British surgery. In September, 1748 at the age of 20, he left his home, Disease."[5] a work more frequently quoted for its glaring errors than for its profound truths, he indicates one of the ways which leads to this ideal, the prevention rather than the cure of disease. He writes: "As disease in general should not only be cured but when it is possible prevented, it will not be improper to show as far as we know how that may be done: for in this disease we can, with more certainty, prevent infection, its origin being known.' He then adds "corrosive sublimate in water, about a grain to 2 to 8 ounces has been known to prevent the catching of the disease."

Hunter anticipated that a time would come when surgery, gaining much from the general advance of knowledge, might be rendered both knifeless and bloodless. I do not speak with irony when I say that Lister's work has brought us appreciably nearer to Hunter's ideal. It is true that its first effect has been to increase a hundredfold the operations practised and to cause an advance into territories never before subdued. The advance was timorous halting and at first so unsafe that the men who led the thought of the day, whose stubbornness was iniquity, whose changeless idolatry was the worship of the images of their fathers, did not hesitate to demand that he who practised such a deadly operation as ovariotomy should be indicted for manslaughter. Lister so taught us that to-day, with little risk and with incomparable advantage to our patients, we who are strong in the faith that our fathers rejected not only attack disease with remedial operations we also seek out and expose, we inspect and study it in its deepest recesses, and in its earliest structural manifestations, sometimes discovering its cause, or at least its impressive antecedent, and often tracing the lines of its gradual advance. We are at last coming to appreciate the reaction of living organs upon each other. As I have claimed on earlier occasions, we have created and are slowly building up knowledge from which our predecessors were completely debarred, not new science but new vision of an old science: the pathology of the living. This branch of surgical learning will continue to grow, and therein surely lies our hope that surgery may one day help to end surgery, by enabling us to discover how these earliest processes of disease may be inhibited. Some claim this as the era of preventive medicine. Is there not preventive surgery also? Hunter was possessed of an ideal. Lister gave the power to realise it. We, too, wage war to end war. "Pereant arma bellica."

THE ALLIES OF SURGERY.

At the end of a long, arduous, and triumphant fore- surgical campaign we, if we are prudent and sighted, shall survey our equipment and our arsenals and consider the strategy of our next advance. The military leader of to-day seeks help from every branch of science, the victorious leader is he who best knows where to seek the help of which he is in need; who has the genius early and quickly to perceive how all new knowledge can be best applied to the art of war. Surgery, too, is warfare: its advance is conditioned by contemporary progress in every branch of science and its virtue lies in the number and the vigour of its allies. Into what alliances, then, has surgery entered with other branches of knowledge?

The science of physics has brought radiology to our aid, and the discovery of the X ray has rendered the living body translucent. After an opaque meal these rays disclose the normal movements of the alimentary canal: and we learn, as in no other way, the functional anatomy of the intestine. Any defect of outline may reveal a structural deformity and perhaps enable us to make a precocious diagnosis of conditions whose terminal stages when neglected are fatal.

The art of the chemist can be allied with that of the physicist, as the work of Graham, of St. Louis, has shown, with the result that the physiology of the liver, the functional anatomy and the pathological conditions of the gall-bladder the association of gall-bladder activity with movements of the duodenum may all be studied by a new method. And this method in alliance with that of the surgeon, realises another stage in our advance towards the prevention of gall-stones, themselves a tardy result of insidious changes originating elsewhere. Chemistry lends its invaluable aid in discovering for us the functional activity of the kidneys, and by its investigation into the cholesterin and calcium content of the blood is helping us to understand some of the problems relating to the functional activity of the liver and gall-bladder. Such conditions as acidosis and alkalosis are impenetrable secrets if chemistry is not brought to our aid.

Physiology by its inclusion in the Faculty of Medicine acquires a double function. It remains a pure science directing its inquiries solely to the advance and perfection of knowledge. But it becomes also an applied science in league with clinical medicine and surgery. As he sees his conquest of knowledge applied practically to the saving of human life the physiologist will be encouraged to yet closer study of normal and aberrant vital processes in man. He, too should stand with the surgeon by the bedside. The great gap between the powers of the surgeon and the aid which the physiologist might give would thereby be reduced, and the reproach removed from his science that, in this sense, it is lagging far behind. The surgeon's activities enable him to uncover the hidden mysteries of early structural changes. He offers new opportunities for the study of normal and perverted function to the physiologist with whom he might inquire into those early functional changes which correspond to and are caused by organic disorder. The surgeon seeks earnestly to know what degree of impairment of function is to be attributed to the textural changes which our new methods have revealed to us. The physiologist may tell us much that we are eager to learn of the effects of our manipulations upon the normal activity of tissues, and of the full or imperfect return of function when diseased tissues have been removed. With his help we may learn what without him we may never learn, the significance and the methods of the causation of early symptoms, and the origins of those pathological changes with whose late mutilations we are, unhappily, only too familiar. With our help he has learnt what otherwise he could not learn that, for example the spleen by an excessive destruction of red cells may produce a condition of jaundice and that the removal of the enlarged spleen results in the disappearance of the jaundice, which is thereby demonstrated to be of hæmolytic origin. Physiologist and surgeon are far more often than is realised necessary to each other, and a closer communion should exist between them. Many of the truths the physiologist endeavours to teach can be demonstrated more clearly in the wards than in the laboratory, and are therefore, because of this human interest, impressed almost indelibly upon the minds of students. The phenomena of cerebral compression of Traube- Hering curves, of Cheyne-Stokes respiration, the symptoms of hyperthyroidism and those produced when the secretion of the thyroid gland is diminished or absent; many of the aspects of jaundice, in addition to the demonstration of hæmolysis as its occasional cause, and of the relations between the liver, the spleen and the bone-marrow; illustrations of the normal and aberrant functions of the kidney; changes in the chemistry and constitution of the blood may all profitably be discussed in the ward rather than in the laboratory or the lecture theatre. Students would then realise from their earliest days the truth, which later comes almost with a shock, that physiology and anatomy are not fundamental subjects but are interstitial, and should grow alongside and be incorporated with the facts of clinical medicine and surgery which they illuminate and explain. Inter- stitial tissue has as one of its functions the carrying of blood-vessels to nourish cells whose activity is dependent upon the richness of their blood-supply. Biology provides the interstitial tissue of surgery:

the activity and the growth of surgery depend upon the nourishment which biology may bring. Unless surgery calls in the aid of all the sciences with which biology is related it will remain as static as ancient geometry, whose figures were drawn once for all. Modern geometry is concerned with function, with the variations of movement by which a figure is described. Surgery's concern in the future will not only be with the states produced, with established organic disease, but with its allies it will help to eradicate some of those variations in function by which perhaps they have been caused, with which they are associated, and by which their presence is declared.

If sometimes we blame Sharpey and his school for the unhappy cleavage between anatomy and physiology,[6] we must at least acknowledge the great debt we owe to him for laying so firm the foundation of new methods for the studying of functional anatomy in man and in animals Physiology, with its offspring biochemistry, has introduced physical and physico-chemical methods;—methods of quantitative observation which have supplemented where they have not supplanted the merely qualitative methods. The brilliant work of Sherrington Lucas, and others upon the nervous system gave us fresh conceptions of it; further advances along their lines were becoming difficult until the application of thermionic valves made it possible, by recording the transmission of impulses in the afferent nerves, to investigate the effects of stimuli upon the sensory end-organs And in the interpretation of symptoms, a study to which my old friend James Mackenzie bent the strength of a most eager and original mind, physiology alone can read the occult significance. In acute pancreatitis there is, as Halsted,[7] a great benefactor of mankind, first told us, a lividity of the face. Why? Is it due to some disordered action of the respiratory system imposed by the closeness of the affected organ to the diaphragm and the structures which lie above it, or is there circulatory stasis, or alteration in the blood pigment?

Physiology is the master of all the methods by which these three possible causes may be quantitatively investigated Estimations of the oxygen saturation of the arterial blood give information of disturbance of respiratory function: information which we may compare to that derived from a measurement of the amount of blood-urea when the renal functions are deficient Estimations of the carbon dioxide combining power of the blood are essential if we are to recognise the presence and the degree of acidosis Circulatory stasis may be gauged by the ethyl iodide method of measuring the circulation rate. Alterations of the blood pigment are detected by the spectroscope and quantitative estimations of abnormal pigments are readily made after the method of Hartridge.

Like the physiologist the bacteriologist is engaged in work which is ranged alongside our own The more he discovers of the offensive powers of bacteria and of the defensive mechanism of living flesh under their attack, the nearer are we brought to our surgical ideal. The alliance between bacteriologist and surgeon has been necessary for the proof that the true estimate of an antiseptic is not measured only by its bactericidal value tested in the laboratory, but also by its power to encourage the blood serum or the tissues themselves to ward off and to break up an attack. Hunter, with the crude methods which were all he had at his disposal, demonstrated the tryptic power of wound discharges and anticipated a part of the admirable work of Almroth Wright during the war. Who could have imagined, when Lister's work began, that to-day we should be able to keep tissues alive in our laboratories, breeding them and growing them in captivity, separating the one kind *from the other*, noting the influence which one type of cell is able to produce on its neighbours and thus coming by the kind of knowledge which John Hunter so earnestly sought, a knowledge of the intrinsic processes of growth and repair? The problem of malignancy is now installed in our laboratories, and the cancer cell is being compelled to yield most reluctantly some of the complex secrets of its bolshevist behaviour

The old art of vital staining, which Hunter learnt from Belchier, of Guy's, has taken on new improvements; by means of suitable dyes we can now select special elements in the living body, trace their movements and note their conduct The experimental embryologist, too, can help us if we seek to know in what manner the various tissues of the body come into existence

These, then, are the allies of surgery in the Great War: biology in all its branches, chemistry, physics, radiology. Never before has the master surgeon had such bountiful resources at his disposal. He cannot afford to neglect a single one of them. The urgent problem of our time is therefore a dual one We must seek to determine the line of advance which surgery will trace in the years ahead, increasing and strengthening our alliances; and we must earnestly discover how the leaders of our army of advance are to be trained. Are the old methods which in their day served so well still enough, or is the form of warfare already so changed, and now so rapidly changing that a new discipline and a wider knowledge are needed?

HUNTER AND LISTER

To answer these questions we must look backward, and, calling upon our past experience, seek in the records of our great masters not so much what their knowledge was, but what methods they pursued as they qualified themselves for great leadership We shall find at once that Hunter and Lister, incomparable among surgeons, each put himself through a long and arduous training, never resting in his inquiries as to the activities of living matter, as to its behaviour in health and its reactions in disease. At the threshold of our survey we recognise that the activities of our two leaders are not unrelated. Hunter's professional life covered the latter half of the eighteenth century, Lister's the corresponding half of the nineteenth century; between them there intervened two generations of surgeons. My distinguished predecessor, the late Sir Rickman Godlee, who gave this oration in 1913 tells us in the life of his uncle Lord Lister[8] that, "Hunter was Lister's greatest hero," that "his copy of Palmer's life of Hunter was marked in many places by pencil notes which show that he was studying it at least as early as 1855," that "a proof of Sharp's engraving of the portrait of Hunter by Reynolds which had belonged to Syme, hung in his study," that "he always spoke of Hunter with reverence." Further, if we turn to the paper[9] which Lister read to the Medico-Chirurgical Society of Edinburgh in March, 1858, on the "Causes of the *Coagulation of the Blood*" we find evidence of his early admiration of Hunter. "The nearest approach," he wrote, "which I have been able to find to such an observation (that blood which is retained in the smaller veins of the body remains uncoagulated) is contained in that inexhaustible treasury of original observations and profound reflection, the works of John Hunter."

If I may borrow a simile from the football field to express the relation of these two great men I would say that it was Pasteur who made the final pass to Lister possible, it was Hunter's captaincy in the scrum that placed Lister in the scoring position. Indeed, we have to admit that while Hunter's resource in midfield has never been excelled, or even approached, and though the ingenuity with which he worked the surgical ball towards the goal remains unsurpassed yet when he was in a scoring position and we are counting so confidently upon a "try," the ball is fumbled and our hopes are foiled. The young surgeon of to-day can learn almost as much from Hunter's mistakes as from his triumphs

The Career of Work of John Hunter.

Let us now examine the discipline to which John Hunter submitted himself to attain his leadership. He is the "Dick Whittington" of British surgery. In September, 1748, at the age of 20, he left his home, an upland farm in the parish of Kilbride, eight miles to the south of Glasgow, and travelling on horseback he entered London in a little under a fortnight, alighting in Covent Garden where his brother William kept a school of anatomy William Hunter was beyond doubt the foremost medical teacher of his time, his best pupils caught from him the spirit of research. Among his inspired disciples were John Hunter, William Hewson, William Cruickshank, Charles White of Manchester, and William Hey of Leeds, the founder of the Leeds Infirmary, the first stone of which was laid in 1767 by Edwin Lascelles, the first Lord Harewood In 1751, after three years of study, John Hunter counted himself a qualified surgeon, he remained in his brother's school to teach and to research, at what salary we cannot now tell, but assuredly it was a small one John Hunter thus entered the critical years of his life, for the career of a young surgeon was determined then, just as it is to-day, not so much by his conduct during the years of pupilage, as by the use made of the period after qualification The problems which a young surgeon first attacks, and the methods he employs to solve them, are suggested to him by the age in which he lives and by the school in which he has been trained In John Hunter's youth a knowledge of the human body was being extended by a skilled use of the art of injection And so we find him in his earlier years following arteries to their ultimate termination, tracing the course of lymphatic vessels, unravelling the structure of the testis and the kidney by means of an expert use of the injecting syringe and of the hand lens He remained in his brother's school teaching and researching until the spring of 1761 when he entered his thirty-fourth year

Here is a list of the subjects he investigated during that period He began to note the earliest stages in the developments of the chick[10] and continued this study to the end of his life, deriving from it guidance for the interpretation of the phenomena of repair and of disease We find him exposing the thoracic viscera, using artificial respiration and noting accurately what happened to heart and lungs when the air-supply was withdrawn and when it was renewed [11] He studied respiration in birds, keeping cocks alive which breathed through their cannulæ inserted in their air sacs instead of through their windpipes [12] He carried out a series of experiments on absorption from the bowel in various animals, the experiments were well planned and skilfully executed, but he drew from them a wrong inference, one which misled him subsequently time after time in the interpretation of the processes of disease He believed that these experiments proved that all the products of digestion were absorbed by the lacteal or lymphatic system and that none entered by the veins [13] Our hero, as we have seen, was often weak when he approached the goal posts We find him tracing out the distribution of nerves in the nose and giving, for the first time, the right explanation of why the fifth pair of cranial nerves should enter into the field of mucous membrane supplied by the olfactory nerves [14] The description he then gave of the descent of the testis [15] and of the vital phenomena which attends that still mysterious operation has never been surpassed He kept a tame kite to prove that a stomach accustomed to a flesh diet could be educated to deal with one which was purely vegetarian, he noted the phenomena of digestion in the stomachs of fish, fowls, dogs, he explained post-mortem destruction of the stomach [16] He placed pieces of raw meat in suppurating wounds and observed the digestive effects which followed, he measured the digestive (or tryptic) action of pus [17] We find him deeply interested in the formation of pus upon the unbroken surfaces of serous and of mucous membranes He began a series of observations on the uses of the vesiculæ seminales [18] and was led thereby to investigate experimentally the potent and mysterious influence which testis and ovary exercise on the development and growth of the body [19] We find him seeking signs to distinguish between tissues in which life was latent and those from which life had already vanished He believed he had discovered the organ of hearing in fishes and sought to discover an explanation of the curious fact that the ovaries of eels were always destitute of ova

As a collector, like Pascal a "ramasseur de coquilles," who often found a pearl of great price, as an observer of incredible industry, gathering facts just for the sake of their individual value and without at the moment any care for their relative significance, for the effect of their impact upon other facts, he ranks second only to Hippocrates But when these facts were stored in his mind and illustrated by a series of specimens, he was by no means inexpert in their interpretation or in raising a general truth from a multitude of singular examples But as we read we seem to be oppressed by the verbal difficulties he encountered The words will not come Even the constructive thoughts may sometimes appear to be absent, puny, or unmanageable He cannot get his mind round them, if by chance we think that he has done so, the splendour of his thought is disfigured by his uncouth language Abernethy is not alone in telling us of Hunter's paucity of language and of his inaptitude in its use; but we need no other evidence than that which his own works rarely fail to give use His letters are the same Illiteracy is not absent from them, though their meaning is often clear enough, especially when express instructions are given It is when Hunter endeavours to rise to abstract generalisations that we see this incapacity chiefly and lamentably displayed Obscurity of language, I believe, even in abstract matters, often means obscurity of thought Words may come after thought, but not long after surely Hunter's defects in language were due in part, no doubt, to the absence of any early education of value, but they were not lessened by his studious avoidance of the work of others His rebuke to Jesse Foot, as brutal and irrelevant as many of Johnson's, would have confounded anybody, but it is irrelevant nevertheless, and it was a confession of his own imperfection

After spending fully 12 years experimenting, John Hunter in the spring of 1761 and in the thirty-fourth year of his age, engaged in the practical work of his profession and was appointed surgeon to the army In the summer of 1763 he returned to London on half pay and commenced practice He bought "a piece of ground called Earl's Court, near the village of Brompton, and two miles from Hyde Park Corner" on which he built a small house Earl's Court, his week-end cottage, was soon converted into a zoological garden and experimental laboratory, many new problems engaged his mind and several avenues of investigation were opened up there, all of them were made to converge on the same subject—the behaviour of living matter under all conditions It was not until 1768, when he was 40 years of age, that his private practice began to grow, enabling him to take a lease of the house, 42, Jermyn-street, vacated by his brother William We may now consider him, after an apprenticeship of 20 years, fairly launched in practice Three years later he considered that his income justified him in undertaking the responsibilities of marriage

We see, then, this leader of surgery of the eighteenth century devoting 20 years of his life to arduous observation and experiment so as to qualify himself for the practice of his art There has probably never been a man in our profession with so wide an intellectual interest, so profound a knowledge of so many varied subjects wholly derived from direct personal inquiry and observation His industry was inexhaustible He had no equal either as physiologist or pathologist, he was already first among comparative anatomists, and was indeed one of the founders of this science He was a naturalist, all subjects in animal and vegetable physiology seeming to attract him All his unequalled attainments as biologist were brought to the service of surgery, in his hospital work, and finally in the largest private practice of his day. Before Hunter's time surgery was a thing apart, independent of all other sciences, ostentatiously aloof from them, and governed only by the experiences and aptitude gained in the day-to-day practice of the art All advance was therefore slow, even when recognisable, and was largely empirical. No physiological knowledge, nor any experimental discovery broadened the old path, or opened up new ones Hunter changed all this Not the least of his achievements was that he made alliances for surgery, and linked it inseparably with biology. Hardly a day passed without some experiment I may quote a statement of his to show how he regarded experiment [20] "In pursuing any subject, most things come to light by accident, that is, many things arise out of an investigation that were not at first conceived, and even misfortune in experiment has brought things to our knowledge that were not, and probably could not have been conceived, on the other hand, I have often devised experiments by the fireside or in my carriage, and have also conceived the result, but when I tried the experiment the result was different, or I found that the experiment could not be attended with all the circumstances that were suggested" This statement helps in some degree to explain the number of apparently unrelated subjects which Hunter explored in his younger years As he opened a new subject he still continued to investigate the old, at the time of his death he had over 50 portfolios in use, each relating to a particular line of investigation

The "misfortune in experiment" has its counterpart in operative surgery An interesting little paper might be written on the Advantage of Error in Medicine We may recall Spencer Wells's operation for an "ovarian cyst" when tuberculous ascites was found, and the surgical treatment of peritoneal tuberculosis inaugurated The same distinguished surgeon, a pupil of the Leeds school, operating upon a *jaundiced girl of 18* for "fibroid tumour of the uterus," discovered that the tumour was not pelvic but splenic; he removed the spleen; in a few days the lifelong jaundice was gone, and the surgical treatment of hæmolytic jaundice was *begun* So McGill, the pioneer in the operation of prostatectomy, precedence in which is so foolishly claimed for others, removed what he believed to be a "tumour at the base of the bladder" When I, acting as his house surgeon, examined the tumour microscopically and found that it was prostatic, I felt that I had the chance to twit my beloved chief with his error His reply, when I told him of his mistaken diagnosis was, "Then why don't we always take the prostate out when it projects into the bladder"?

The Career and Work of Lister

When we compare Lister's preparation for professional leadership with that of John Hunter we are impressed rather by the resemblance than by contrast Lister, the greatest material benefactor of mankind that the world has ever known, began his medical studies at University College, London, at the age of 21, in 1848, exactly a century *after* John Hunter had settled down to his work in Covent Garden In the hundred years that had passed medical education in London had undergone a revolution, voluntary schools had almost disappeared, to be replaced by the organised schools and colleges with which we are familiar to-day John Hunter was Scotch, Lister English, his ancestry coming from Yorkshire and Cumberland John Hunter owed much to his brother, Lister still more to his father, who was not only a successful man of business, but also a Fellow of the Royal Society William Hunter, who impregnated the mind of his brother, drew his own inspiration and owed his intellectual guidance to the Munro-Cullen school of Edinburgh Lister was early influenced by William Sharpey and by Wharton Jones both Edinburgh men, steeped in the traditions of this very school After qualifying in 1851, and taking the Fellowship of this College at the age of 25, Lister's first research was begun; it was concerned with the contractile tissue of the iris [21] The injection syringe, the new instrument which had served Hunter so well, had been displaced during Lister's youth by the microscope We rejoice, nevertheless, to notice that when Lister applied this new instrument to the tissue of the iris it was the function rather than the form of this structure which excited his interest In this investigation and in another,[22] begun in 1852, "Observations on the Muscular Tissue of the Skin," we recognise that, influenced by William Sharpey he had become familiar with discoveries made in other countries, notably with those of Kolliker in Germany But clinical work was not forgotten, and a house surgeoncy at University College was followed by perhaps the most critical event of Lister's life In tracing the motives which have directed the progress of medicine we are constantly reminded of the influence and the power of great teachers Such men are gratefully remembered by posterity, not so much for the work which their own hands or minds have created or have modified, not for their written words which so soon seem to possess little more than an antiquarian interest, not for their spoken words which, though at the moment of their delivery they may walk up and down in the hearts of men and stir them to new thought or to great action, yet seem so frail and cold and lifeless when the morning comes, not for any of these, but for the spiritual legacy they bequeath to those inspired by their own zeal and trained in their own methods to seek the truth in eternal principles It is this which gives posthumous life, the true immortality

Not the least of the claims that John Hunter makes upon our reverence is that he was the first founder of a school of surgery He was not distinguished as a teacher "He had not the happy talent of displaying the stores of his mind, nor of communication to others the same perception of the importances of his facts and opinions as he himself entertained" [23] Abernethy said his language was "inelegant and often coarse," "his delivery heavy and unengaging," "his method confused with attempts to find words for thoughts, or else to read from little scraps of paper" Yet despite these unattractive or even repellent qualities, men who themselves influenced surgery for generations afterwards, whose influence still survives, Abernethy, Astley Cooper, Cline, Everard Home, Blizard, all boasted of being his pupils, and taught his method until it became, and still remains, a tradition in their schools and from them has spread to every school of medicine in the world where Hunter is recognised, unchallenged, as the founder of scientific surgery My old friend, Dr Finney, of Baltimore, in his recent address before the Hunterian Society, an address containing much information new to us in this country, speaks eloquently of the germinative influence of John Hunter upon American surgery. He tells us how John Morgan and William Shippen, the founder of the first medical school in America, from which the present medical department of the University of Pennsylvania descends, were "much influenced" by John Hunter, and he adds "so virile and dominating was his influence that it may readily be recognised and transmitted like other distinguished hereditary traits" And again, "The seed sown by John Hunter is being continually replanted and perpetuated by succeeding generations" in America Finney quotes Dr Welch, the intellectual parent of so many sturdy sons, as saying of the "Father of American surgery," "Physick was almost as much a mouth-piece of the doctrines of John Hunter in America as was Abernethy in London" In his "Surgical Memoirs" J G. Mumford writes "The best American surgery grew out of English surgery with Hunter as its prophet" Hunter was the lodestone which attracted men who proved to be the pioneers of surgery in that great country where our Art is *practised* by its highest exponents with unsurpassed skill and safety Mumford no doubt remembered that the first professor of surgery in his own University of Harvard was Collins Warren, distinguished son of a distinguished father, a pupil of Astley Cooper, himself the chief of Hunter's disciples, and a teacher who drew men to him from afar So, in like manner, the debt we owe to Italy must forever be acknowledged when we remember that it was the magnetism of Fabricius that drew the youthful Harvey to Padua But for Fabricius and the magic of his work the discovery of Harvey, the great glory of English medicine, might not have been made for generations

William Sharpey, whose lectures "inspired me with a love of physiology that has never left me," had not only Lister's future, but also all that this meant for mankind in his own hands when he sent Lister to Edinburgh to the "safest surgeon" of his day, James Syme It was an almost incredible exodus When the Hunters came southwards they followed a national habit established for centuries, and never permitted to fall into disuse a habit which incited the characteristic invective of Samuel Johnson When Lister went northward he founded a new tradition and made a novel breach in a custom which seemed to have become as firmly accepted as a law of nature Lister's most distinguished successor in his chair of clinical surgery, my old friend Harold Stiles, made the same adventure, to Scotland's great advantage.

London hardly notes and seems but little disturbed by the arrival and the progress in her midst of young medical men from Edinburgh (Whatever would she do without them?) Edinburgh, one may suspect, raised her eyebrows when she saw a young doctor from London established as Syme's house surgeon, and she must have rubbed her incredulous eyes when, within two years, she saw him become an extramural lecturer in surgery within her own stronghold It is quite impossible to exaggerate the importance of this teaching appointment on Lister's future He met his students—the ultimate number in his first class was seven—on Wednesday, Nov 7th, 1855 Lister believed, as Hunter had believed, that the beginning of surgery was a knowledge of the process of inflammation; and accordingly he had resolved before his lectures commenced to obtain a new first-hand acquaintance with inflammatory processes as watched in living tissues Clearly he realised long before the humblest of his intellectual descendants the need to study the "pathology of the living" A frog was caught in Duddington Loch; surely the greatest frog in history, honoured by being made the subject of this research Why did not someone suggest to Lister when he was granted Arms that this frog should be immortalised in heraldic device? The web of this frog's foot gave all the necessary opportunities for the inquiry Lister had many new advantages over Hunter; he knew that the tissue he examined was made up of living units—cells! He had at his disposal a powerful microscope, which could mark the behaviour of these cells; and Claude Bernard, in 1853, had taught him the existence of vasomotor nerves. It was during the examination of the frog's web that Lister made a biological discovery of the highest importance—one which experimental biologists are still exploiting—that pigment-containing cells, such as are seen in the frog's web, give more easily visible, and more delicate, reactions than any other kind of living cell when subjected to a physiological or a pathological stimulus This quality enabled him to study the effects of inflammation in terms of individual cells He was able to prove that these pigment cells still gave vital responses 15 days after the leg had been amputated

The list of researches carried out by Lister between the time of his arrival in Edinburgh in 1853 and his appointment to the chair of surgery in Glasgow in 1860 would almost suggest that he was seeking to fit himself to become an experimental physiologist or pathologist rather than a surgeon I would earnestly emphasise this point, for its significance in Lister's day was far less that it is to-day when the full harvest of his work is ready to be gathered In most of these researches we can clearly see the strong influence of John Hunter. It is not accident surely that the men who have done most for surgery trained themselves rather as research workers than as practitioners, that they revelled in and set out to master one problem after another in biology. Lister's acknowledgment of the immense influence of Hunter upon him is not in the least overstrained If the spirit of Hunter watches over his museum and this College, as we hope it may, how infinite must be its pride in the thought that the one man greater in service than Hunter himself was his direct intellectual offspring

Let me recall the names of a few of Lister's early papers: That "On the Flow of the Lacteal Fluid in the Mesentery of the Mouse,"[24] begun in 1853 and published in 1857, is a direct extension of Hunter's experiments on absorption,[25] the communication on "The Persistent Vitality of the Tissues"[26] is founded upon observation made by Hunter himself on the same subject The studies on "Coagulation of the Blood" began by observing what happened in the veins of "sheeps' trotters" taken from the shambles By devising new and critical experiments he was able to carry the knowledge concerning coagulation to a point far beyond that which Hunter had reached a century before him Yet his methods were clearly modifications of theirs Lister's vocabulary, indeed, was still that of Hunter, for he spoke of the "solids" of the body, of "preternatural stimuli", of the "disposition of the tissues"; of "inherent tendencies", and of "sympathetic irritation"

The events which followed Lister's arrival in Glasgow are too well known to all the world to need more than the briefest recapitulation Lister was then 33 years of age, almost the same age as Hunter when he joined the army as a surgeon As a result of seven years of a preparatory experimental investigation, conjoined with a wide clinical observation which was closely related to it, he had become immersed in all the problems relating to inflammation and suppuration He had already formulated a hypothesis that suppuration was due to putrefaction and in 1865 was ready to put his supposition to a practical test Pasteur's epochal discovery that putrefaction was due to "germs" set matters going Lister wrote[27] —

> "To prevent the occurrence of suppuration, with all its attendant risks, was an object manifestly desirable, but till lately apparently unattainable, since it seemed hopeless to attempt to exclude the oxygen, which was universally regarded as the agent by which putrefaction was effected But when it had been shown by the researches of Pasteur that the septic property of the atmosphere depended, not on the oxygen or any gaseous constituent, but on minute organisms suspended in it, which owed their energy to their vitality, it occurred to me that decomposition in the injured part might be avoided without excluding the air, by applying as a dressing some material capable of destroying the life of the floating particles"

Lister was first of all concerned with the destruction of organisms after they had obtained access to wounds He knew of the experiments with the Carlisle sewage, and of the bactericidal properties of carbolic acid He observed carefully the effects produced upon living tissues by antiseptics and concluded that the reparative processes in a wound were not thereby weakened We are apt, however, to forget the gradual change that came over Lister's views, and the effect this had upon his practice, how he came to a full realisation of the essential powers of defence possessed by the living tissues, and of our obligation to protect and, if possible, to increase them Sir Rickman Godlee, who knew more of Lister than any man, has written that Lister before 1881, when he first told the world of his changed opinions,

> "had long recognised and taught that healthy living tissues exercised an inhibiting influence on the growth of micro-organisms He therefore began to wonder whether, if only slightly damaged, for example by the incision made by a very sharp knife, the living tissues of any wound might not be able to deal with a certain number of germs by their own efforts"

This we gleefully observe is a return to Hunter's work in which he recognised the "powers," "disposition," and " action " of living tissues. It may not be inappropriate to quote Lister's own words. He writes [28, 29] —

> "The original idea of the antiseptic system was the exclusion of all microbes from wounds " Again, " During the operation to avoid the introduction into the wound of material capable of inducing septic changes in it, and secondly, to dress the wound in such manner as to prevent the subsequent entrance of septic mischief " Again, " In wounds already septic, attempts are made with more or less success to restore the aseptic state " Again, " In speaking of the antiseptic system of treatment, I refer to the systematic employment of some antiseptic substance so as entirely to prevent the occurrence of putrefaction in the part concerned, as distinguished from the mere use of such an agent as a dressing", and further, " I always endeavour to avoid the direct action of the antiseptic substance upon all tissues "

The distinction between the preventive and the curative use of antiseptics is in many respects that existing between, on the one hand, the power of a germicide as determined by experiments in vitro, and, on the other hand, its capacity to destroy organisms when it is introduced among the living and the dead tissues of a wound In the former there is a direct conflict, a clean fight, between the microbe and the chemical agent Few or none of the many intervening conditions are present which have to be considered when a bactericide is introduced into a wound cavity wherein there are multitudes of actions and reactions which even now seem very obscure and are so often conflicting.

HUNTER'S ANTICIPATION OF MODERN PROGRESS

We may, therefore, regard Hunter and Lister as bridge-builders , it is out of a multitude of scientific observations, of apposite inferences, and of wide generalisations that such bridges are built, stone by stone, arch by arch Posterity will perhaps remember only the one bridge, permanent, indestructible, all sufficing, of Lister Across that bridge we have swarmed, a triumphant host, and a vast new territory has met our almost incredulous eyes Hunter was forever building bridges, ambitious in design, firm in their foundations, but always left unfinished Some day new architects will come and given them the full span which Hunter surely meant them to have It is remarkable to note how often he anticipated the lines along which we see that modern surgery is making its advance. Cultures of both benign and malignant tissues are now being kept alive by methods which, devised by Dr Ross G Harrison while studying the growth of fibres from the nerve-cells of a tadpole, have been rapidly developed by Alexis Carrel John Hunter, too, tried his hand at experimental embryology He " exposed the little animal (the chick embryo) by putting it into water heated to about 104° F just covering the egg " and " hoped to keep it alive by these means and observe in the same chick the whole progress of growth, but it soon died "; therefore, he says, " I was obliged to have recourse to a succession "[30] He was an experimental surgeon, as may be shown from the following quotation[31] from one of his lectures :—

> " Here is the testicle of a cock, separated from that animal and put through a wound, made for that purpose into the belly of a hen, which mode of turning *hens* into cocks is much such an improvement for its utility as that of Dean Swift when he proposed to obtain a breed of sheep without wool The hen was afterwards killed and the testicle was found adhering to the intestines, as may be seen in this preparation where the parts are preserved."

He devised and carried out experiments to ascertain whether the growth in a cock's spur is due to a " disposition " inherent in the spur or derived from the constitution of the cock He excised spurs from the legs of cocks and implanted them in their combs to note the rate of growth under such unfamiliar surroundings. The first vital stain ever used was madder , it was introduced to the notice of biologists in 1764 by John Belchier, surgeon to Guy's Hospital by its experimental application John Hunter revolutionised our knowledge of bone growth and bone decay.[32] In the hands of Prof A V Hill the measurement of heat in living tissue has become the most delicate and certain indication of the nature of their vital reactions The manner in which living matter reacted to the application of heat and cold, and the degree of heat generated in living tissues, Hunter made the subject of an endless number of investigations, all with the practical view of ascertaining how much or how little should be done to keep damaged human tissues alive [33] He was, as we have seen, an experimental physiologist and also an experimental pharmacologist [34] He was psycho-analyst[35], he tried to inoculate an ass and a bitch with the virus of syphilis.[36] He preached the doctrine of operating at the earliest possible stage of a disease, and placing himself in the position of the patient said, " Nor do I go further than I now think I would have performed on myself were I in the same situation "[37] He performed experiments on the sensitive plant which are now being repeated [38] These are only some of the points in which Hunter has anticipated modern progress

VISIONS OF THE FUTURE

So much for the past in its relation to our greatest men What of the future ? Looking forward I humour my fancy and indulge my dreams Imagination, Keats tells us, may be compared to Adam's dream—he awoke to find it truth The art of the surgeon is the pillar of his science, and it is for science to discover how that almost perfect art may now be used to the fullest advantage We eagerly await the day when disease shall not require to be checked in high career, but shall be blighted at its origin, or even denied existence, when our weapons of war shall be laid aside. That day may yet be far away, but already beyond the distant hills we see promise of the dawn It does not perhaps so much or so deeply concern ourselves as those who soon must take up our task, and lead the hosts whose victory shall attain our high ideal In due time, and in accord with ancient precedent, this country of ours, the fruitful mother of so many gifted sons, shall raise up in our schools the youths who shall go forth to conquer a crown They will be best equipped who keep to the course, recall the methods, and are imbued with the ardent spirit of the two famous men whom we praise to-day, the two greatest surgeons the world has ever known

Our youths must be prepared for self-sacrifice, for arduous discipline, perhaps for the most heart-breaking rebuffs, for the stern or even bitter criticism of their fellows But there never was a time so rich in promise, so laden with rewards for those who labour with sincerity and truth. They will not travel alone. The whole army of science is in league with them, moving forward with incredible speed, eager to lay at their feet the triumphs of its astounding conquests The responsibilities which rest on them, the intellectual accomplishments, and the dedication of their lives demanded of them, are enough to cause the stoutest heart sometimes to falter. Yet, armed with the sword of the spirit and the breastplate of faith, they will remember that the happiness of life lies in its responsibilities, that true joy is found in the quest for what may after a weary journey prove unattainable Ahead lies the noblest of tasks to which they may consecrate themselves . for the lives of men are in their hands, the love, the happiness, the whole welfare of mankind We need not fear They will be worthy of their charge. God counts not result but effort

SOME OBSERVATIONS ON THE DIAGNOSIS OF HEPATIC DISORDERS.

By DANIEL T DAVIES, M.B , B Sc Wales,
M R C P Lond ,
ASSISTANT CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL

The administration of galactose as a means of diagnosing liver abnormalities and also for estimating liver efficiency has been largely confined to German clinics Like glucose, it is a monosaccharide, and is absorbed direct via the portal circulation into the liver In health the ingestion of 40 g results in no hyperglycæmia, and no galactose appears in the urine, as the glycogenetic capacity of the liver in health is sufficiently powerful to transform the ingested sugar into glycogen with the passage of but small amounts into the peripheral circulation, and in consequence only a small increase, if any, in the blood-sugar value It must, however, be administered in a pure state before any reliance can be placed on the results obtained.

As early as 1906 Bauer[1] suggested the use of galactose, and Brasch[2] in 1908 gave a review of the earlier literature, pointing out that galactose builds up glycogen and that it is absorbed uniformly from the alimentary tract In 1918 Kahler and Machold[3] made elaborate investigations on the value of galactose. They found that normally there is less than 30 mg. per 100 c cm. difference in blood-sugar at the end of one hour after ingestion of the sugar, and that the maximum difference of over 100 mg. was obtained in cases of catarrhal jaundice They came to the conclusion that it has yet to be established that galactosuria and hyperglycæmia are of any service in estimating hepatic efficiency other than derangement of the hepatic control of carbohydrate metabolism. Their practice was to estimate the blood-sugar one hour after the ingestion of the sugar and to obtain in grammes the amount lost in the urine It is significant that they obtained negative results in cholelithiasis, and that syphilitic hepatitis yielded markedly positive figures

Richard Bauer[4] in 1924 gave a very detailed account of the necessary precautions as regards purity of the sugar, &c , its advantages and its limitations This observer placed reliance on the urine only—on the amount of sugar lost during the four hours following ingestion But Kahler and Machold pointed out that there is often galactosuria with no rise in blood-sugar, and especially is this so in renal-leak cases Taken alone, the amount that has escaped in the urine becomes too unstable a guide to liver efficiency Rowe[5] in 1924, working on the metabolism of galactose, believes that the dose is little influenced by age, weight, or body area. “ It is found to be apparently directly dependent on sex, and influence of mammary glands is suggested as a possible explanation ” The female, he says, is able to tolerate more than the male. There may be some evidence to support this statement, which should be remembered when the liver efficiency of pregnant women is tested

The German observers have attempted by a study of the sugar to estimate the degree of liver damage and even base their prognosis on it alone, and Bauer says “ galactosuria is often the only positive sign of abnormal liver function ” It is certainly misleading to depend on the urinary findings, as the threshold for galactose is not at all definite, and traces appear in the urine of the majority of healthy people Even the blood values cannot, if taken alone, be always helpful. Indeed, they may be misleading In this paper some evidence is offered to show that the galactose test, taken in conjunction with other simple tests, will prove to be a help and guide in distinguishing various cases of jaundice It is not specific, and no interpretation should be based on it alone Not only is a negative result obtained in normal cases, but also in those cases of jaundice, however deep, which are mechanical in origin A stone in the duct, a carcinoma of the pancreas, enlarged glands at the hilum, all produce the same negative result provided no change has taken place in the liver cell itself. Their glycogenetic power is unimpaired—an activity which depends upon a healthy liver cell If in any of these cases known to be mechanical in origin the result turns out to be positive it signifies that some damage has already taken place in the parenchyma R Bauer in his paper warns the surgeon who performs cholecystectomy that if the galactose test is positive in such a patient chloroform must not be used, as a further cellular intoxication may flare up a fatal hepatitis which was smouldering before the operation

During the investigations on which this communication is based it was customary in all cases presenting jaundice to examine the blood for the following bilirubinæmia, by the Fouchet and van den Bergh tests, estimation of cholesterol content of the blood, and the galactose tolerance test The urine was also examined for bile salts and pigments and urobilin In some cases the bromsulphalein test was also performed By the summation of these tests one could arrive at a conclusion with some degree of assurance whether an icterus was obstructive, intrahepatic, or extrahepatic, a conclusion which many regard as being very simple clinically. This is true of jaundice in the late stages of obstruction, but, while clinically indefinite in the early stages, one can show definite laboratory changes by these tests even then Again, clinical conditions are never cut and dried There is some degree of obstruction in all toxic cases, and there is some hepatic cellular damage in all prolonged mechanical cases blurring the diagnosis, so that if we obtain by a series of tests a real knowledge of the dominant factors, this may be a real and timely help

The Galactose Technique

The sugar should be tested beforehand for its rotatory power, which should be at least a specific index of 76° Less than that amount indicates too large a degree of impurity Forty grammes are dissolved in about 400 c cm of water and given to the fasting patient, whose resting blood-sugar has been taken immediately before The sugar is estimated in the blood every half hour for two to three hours afterwards The urine is also collected up to the fourth hour and the amount of reducing substance present estimated This is the amount lost out of the 40 g ingested Alone, this observation on the urine is open to many errors, as the threshold varies enormously in normal people, while in nephritic cases the kidney may entirely fail to excrete it However, in people whose blood is difficult to obtain the amount in grammes lost via the urine is a rough index of the hepatic damage, provided that there was no sugar present in the urine before giving the galactose In diabetes the test is, of course, valueless Again, if much ascites be present, it has been shown that the absorption of the sugar via the alimentary tract may be delayed, and the sugar still excreted even for five to six hours following the ingestion If the sugar in the urine is estimated by means of a polarimeter, as the sugar is galactose, a correction

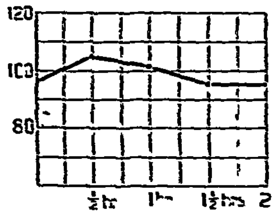
must be made since its rotatory power is 82° compared with 56° for glucose. If the amount is multiplied by ⅔ the result approaches accuracy.

Normal.

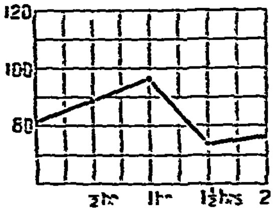
The ingestion of 40 g. of galactose does not result in an increase of the blood-sugar in normal persons Chart 1 shows the blood-sugar values in such a person. There may be some slight increase, but in any case it is never greater than 30 mg. The urine contains always less than 1 g. in the three hours

CHART 1



Showing blood-sugar values in normal persons after ingestion of 40 g of galactose

CHART 2.



Galactose test The curve obtained in carcinoma of the pancreas with obstructive jaundice

Bauer tabulated his urinary findings as follows: Normal. 0–1 g.; high normal. 1–2 g; positive, 2–3 g; high positive. 3–12 g. The greatest loss that has been observed in this series is 6 5 g

Jaundice of Mechanical Origin.

Mechanical causes of jaundice also yield a negative result, provided that the jaundice has not been prolonged Chart 2 shows the curve obtained in carcinoma of the pancreas in which the jaundice is obstructive

M. C Obstructive jaundice. Carc. pancreas. Fouchet test strongly positive; van den Bergh. direct reaction immediate, cholesterol. 212 mg per cent.

Galactose tolerance test. (40 g. given):—

		mg per cent.

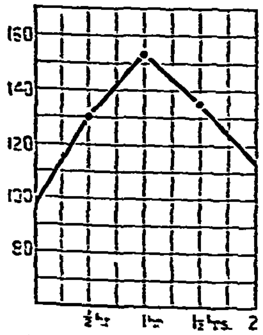
„ „ 1 „ „ „	..	98
„ „ 1½ „	..	72
„ „ 2 „ „ „	..	75

0 8 g. of galactose appeared in the urine during the following four hours.

Bile salts and bile pigments: positive. Urobilin: negative Diastase: 28 units. Fæces: total fats 54 g per 100 g dried fæces. Fatty acids 28 g per 100 g dried fæces. Bile pigment absent from the fæces.

CHART 3



Galactose test in a case with obstructive lesion, but showing some intolerance

Although the patient was emaciated to a great degree, and the jaundice was intense and of over a month in duration, the glycogenic function of the liver as judged by this test was intact.

In a certain number of cases in which the main findings point to an obstructive lesion the galactose test may be positive. This is true when the liver itself is riddled with secondary deposits from a malignant growth which itself is causing the main obstruction. Chart 3 shows this condition—the massive secondary deposits causing pressure on and ultimately destroying a large portion of the liver parenchyma.

H P. Jaundice, 14 days loss of weight two years. Fæces pale Urine dark van den Bergh: immediate direct Fouchet: strongly positive: cholesterol: 186 mg per cent

Galactose tolerance test:—

		mg per cent
Blood-sugar before administration	..	99
„ „ ½ hr. after „	.	130
„ „ 1 „ „ „	..	151
„ „ 1½ „ „ „	.	135
„ „ 2 „ „ „	..	111

Urine contained 2 3 g of galactose during the following four hours

Diastase: 28 units; bile salts and bile pigments: positive; urobilin: negative.

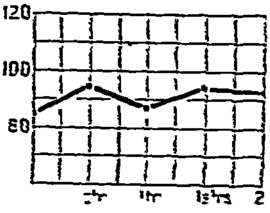
In this case the dominant clinical and laboratory findings pointed to an obstructive type of jaundice. but the somewhat positive galactose test was later substantiated by the autopsy, showing large secondary carcinomatous deposits in the liver tissue itself.

If the cause of the jaundice is known, such as a stone in the duct, and the patient yields a very positive result this signifies that there is some derangement of the liver parenchyma and this may explain many cases which do not progress rapidly after cholecystectomy, &c. The test can, therefore, be of value in signifying the state of the liver prior to and after a biliary operation

Extrahepatic Jaundice.

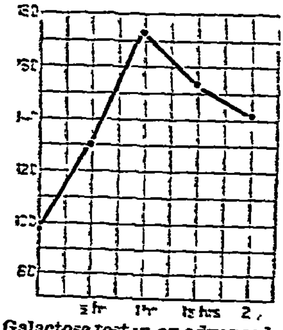
Negative results are not only obtained in mechanical cases, but also in extrahepatic cases of jaundice, such as pernicious anæmia, which indeed is a true hyperbilirubinæmia also acholuric jaundice and in those cases of jaundice which develop after a hæmothorax or hæmoperitoneum. It is in these types that one is so anxious to know whether an infection has occurred and if the liver is involved—a complication which would be followed by a disastrous prognosis—and it is in these types that the galactose test is equally negative giving proof that the liver cell is not involved and that the condition is a mere transient hyperbilirubinæmia, a state entirely due to the increased breaking down of the extravasated hæmoglobin by the endothelial cells, and forming bilirubin. Pernicious anæmia does not give consistent negative results: it may be markedly positive in the terminal stages, due to the fatty degeneration present in the liver parenchyma

CHART 4.



Galactose test in an early case of pernicious anæmia.

CHART 5.



Galactose test in an advanced case of pernicious anæmia.

Chart 4 shows the negative curve obtained in a case of pernicious anæmia—an early case which contrasts with the more advanced case, in which presumably the fatty changes that have occurred in the liver render that organ incompetent as shown in Chart 5

T B Pernicious anæmia (extrahepatic type of jaundice) An early case with: red blood cells: 3 950 000; white cell count. 6000; colour-index: 1 1: Achlorhydria van den Bergh: indirect: Fouchet: negative: cholesterol. 110 mg. per cent.

Urine 2 3 g of sugar No bile pigments or salts Urobilin positive

Toxic Jaundice

The most marked positive results are obtained in catarrhal jaundice Bauer states that phosphorus poisoning and acute yellow atrophy give very high values; no cases of this kind are included in this series In catarrhal jaundice the result is positive in the very earliest stages, and may persist for a much longer time than the clinical state indicates Indeed in some cases it may remain positive for a prolonged period, and, in this connexion, it is interesting to note that the German workers believe it is at this stage that many a cirrhosis begins to develop Chart 6 shows a typical catarrhal jaundice with pronounced intolerance

„ „ 2 „ „ „	90

Urine contained 1 4 g of galactose

The greatest difference now is 38 mg, whereas before treatment it was 118 mg

Cirrhosis

Cirrhosis of the liver yields variable results, and this is doubtless due to the hypertrophy that exists in this condition As enlarged cirrhotic liver is more likely to give a negative result than a small atrophic one Included in the series is a case of strong alcoholic history with much ascites but little emaciation or sign of toxicity (Chart 10) The galactose test was normal showing that the hypertrophy was overbalancing the abnormality, and the fibrosis was mainly portal The bromsulphalein test was also negative

M. W Cirrhosis of liver Much ascites No jaundice No emaciation No evidence clinically of any toxicity van den Bergh indirect 2 units, Fouchet test negative, cholesterol 83 mg per cent.
Galactose tolerance test —

The prognosis in this case is much better than in the following one Here although the ascites is a tremendous burden to the man there is far less evidence of a liver cell destruction than in the case of A. B (Chart 11), which shows such galactose intolerance

If an operation for cirrhosis were devised in which the ascites were relieved, this would be the type of case which would yield good results

Charts 11 and 12 show the opposite condition in which although the clinical findings were far less definite the ascites only being present in one and the liver not enlarged in either, yet the galactose test yielded very positive figures In these cases the symptoms were more prominent than the signs A fatal complication and an early termination would be more likely in such cases than that of Chart 10.

Urine Bile salts and pigments · negative; urobilin: faintly positive.

Although the evidence is slight. the facts point to a toxic type rather than an obstructive. The after history proved that this condition was a transient hepatitis

Bauer has shown that in exophthalmic goitre a positive result can be obtained, but in this connexion it must be remembered that he only *noted the amount* lost in the urine and glycosuria is not by any means uncommon in this condition.

In this series all cases of jaundice were examined in the following order.—

(1) Duration. (2) Clinical diagnosis (3) Blood: Urea, Non-protein nitrogen, uric acid cholesterol, van den Bergh, Fouchet, galactose tolerance test. (4) Urine. bile salts, bile pigments, urobilin, diastase, sugar

Armed with the results of these tests one can arrive at a diagnosis which is within the range of great probability. It would be impossible to mistake an incipient jaundice due to neoplasm for a jaundice due to a benign catarrh Also in those cases which have a lithitic history with radiographic confirmation. if the tests are positive, they give due warning of a derangement of the hepatic cell itself. The blood-urea and non-protein nitrogen, &c, have been done to give an assurance that the nitrogen eliminating powers of the kidney are functioning

The *cholesterol estimation* has proved to be of great value It would be unwise to draw any such conclusions as that the patient has one or more gall-stones or a cholecystitis from the cholesterol estimation alone, but as surely as the content is high —i e , not less than 180 mg —it points strongly to an obstructive jaundice In only one other condition are such high cholesterol figures obtained, and that is the nephrosis of Epstein Cholesterol, like the bile salts, passes in a circle through the blood—>liver—>ducts—>intestine—>blood, with a variable loss in the fæces In obstructive jaundice this route is impeded and there is a consequent damming back in the circulation, producing a high figure The hypercholesterolæmia that is supposed to be present in cases of cholecystitis has not been confirmed—in fact, the gall-bladder can be full of pathological conditions, the patient can be persistently fed with cholesterol containing substances, as long as the ducts remain patent, little increase can be made out in the cholesterol content of the systemic circulation.

Some cholesterol estimations obtained in various diseases are here appended —

		mg per cent
H R	Gall stones and cystitis	111
E W	Jaundice—carcinoma pancreas	250
A L	Cirrhosis of liver	95
F G	Enlarged liver without icterus (cirrhosis)	78
R B	Syphilitic liver	105
M U	Obstructive jaundice	305
H H	Cirrhosis	109
M C	Malignant jaundice (obstructive)	212
M M	Toxic jaundice	140
M N	Cirrhosis	83
B M	Nephrosis (28/10/25)	517
	(6/11/25)	444
	(24/11/25)	240
C T	Diabetes	127
F T	Diabetes—diabetic coma	210
J S	Obstructive jaundice	340
P A	Pernicious anæmia	97
A	Obstructive jaundice	333
	Addison's disease	78
	Carc breast, sec liver, obstructive jaundice	308
A B	Cirrhosis	131
D T	Acholuric jaundice	145

It can be seen, therefore, that in cases of jaundice, if the cholesterol is above 180 mg per cent , it points to an obstructive type

Van den Bergh Reaction —The utility of this reaction has not proved to be proportional to the initial reputation it gained Although extremely disappointing in the laboratory, and being definite only when there are at the same time definite diagnostic facts equally well observed at the bedside, it has nevertheless brought into prominence Aschoff's work on the reticulo-endothelial system It has also brought to light the extrahepatic type of jaundice, and has made it possible to estimate the bilirubin content of the serum—an estimation undoubtedly of great value Success has not resulted when an attempt has been made to differentiate the various types of jaundice by the intensity of colour and time of appearance The only satisfaction that can be obtained is whether the van den Bergh is direct or not—to be able to diagnose and divide into any further groups is highly hypothetical The use of caffeine sodium salicylate to enhance the colour of the diazo-reaction has also yielded little profit Further studies are now being carried out on the constitution of the bile pigments in various types of sera, and an attempt is being made to ascertain the difference between the bilirubin that has passed through the hepatic cell and that which has not passed, a difference which becomes almost doubtful, except for a possible difference in quantity or a difference intimately related to the duration of the jaundice It is known already how easily bilirubin changes to biliverdin—how the marked changes in colour occur when the reaction is changed—how even the reaction (alkali or acid) of stomach contents that are tinged with bile can be judged by the green or blue colour of the contents It is possible that similar colour changes—but quite intermediate—occur in bilirubin in sera in various conditions and during various stages of the jaundice These or other facts may explain the uncertain colour changes observed in alcoholic extractions that have been advocated as differentiating facts, but which have so frequently proved valueless Except therefore for the estimation of the degree of bilirubinæmia, little proof has been forthcoming that the van den Bergh reaction adds any more information in the diagnosis of jaundiced cases It is indeed manifest to an observer who has attempted any work on the condition of jaundice how delicate the eye sense is, and how little is gained by any further laboratory investigations of the pigment by the van den Bergh reaction

Fouchet Test —This test is always regarded by all who have experience of it to be highly valuable It was introduced to demonstrate the presence or absence of a pathological degree of bilirubinæmia It is supposed to show an amount of 1 to 60,000, but it promises to be even more delicate

Bile salts in the urine indicate the jaundice to be of obstructive origin Bile salts are sometimes found to be present when no icterus is present—dissociated jaundice of the French—this is little understood

Urobilin —The presence or absence of urobilin in the urine has proved to be of great value, if present it generally supports the diagnosis of a jaundice to be due to some toxic state, in mechanical cases it is always negative

A *diastase* content in the urine of over 50 units assists in attributing the cause of the icterus to a primary pancreatic lesion

Example of icterus due to obstruction .—

Blood van den Bergh reaction direct immediate, cholesterol content 220 mg per cent , galactose tolerance test 100, 110, 121, 109, 94 Urine urine sugar less than 1 g, bile salts and pigments positive, urobilin negative

Example of an icterus toxic in character (catarrhal jaundice) —Blood van den Bergh reaction indirect, cholesterol content 126 mg per cent , galactose tolerance test 94, 120, 160, 145, 126 Urine sugar content in three hours 5 5 g , bile salts negative, bile pigments and urobilin positive

Example of an extrahepatic jaundice (pernicious anæmia) —Blood van den Bergh reaction · indirect , cholesterol content 97 mg per cent galactose tolerance test 94, 112, 108, 99, 81 Urine No galactosuria , bile salts, bile pigments, and urobilin negative

The three cases detailed are examples of the three great divisions of jaundice, and the galactose test yields positive results in the second group only

The two factors to note in the galactose tolerance test are the maximum difference obtained in the blood-sugar level and the amount in grammes of reducing substance present in the urine A difference of over 30 mg in blood-sugar indicates some positive degree, frequently as much as 160 mg difference is obtained The second factor is the amount in grammes lost out of the 40 g ingested, and which must always be estimated Any amount of over 2 g proves a decided hepatic deficiency As the threshold for galactose is less than that for glucose, sugar appears in the urine with a blood-sugar value that is often not higher than 130 mg , so that one sees quite frequently a small degree of galactosuria even in health after the administration of 40 g In small children it is customary to modify the dose, but no rigid standard has been adopted

Summarising the pathological states, it is seen that in *obstructive jaundice* the galactose test is negative, but the van den Bergh reaction is direct, the cholesterol content is high, and bile salts are present in the urine, while in *toxic and infective jaundice* (including the hepatitis called catarrhal jaundice) and in any other lesion of the hepatic cell the following are the salient features · a difference of blood-sugar far exceeding 30 mg per cent , a loss of over 2 g in the urine, a normal cholesterol content, a van den Bergh reaction which is indefinite with generally bile pigments only in the urine, and lastly, an urobilin reaction which is strong in degree

In *extrahepatic jaundice* the main features are on the negative side—a negative galactose test, absence of urobilin in the urine, and the normal cholesterol content being the main aids in diagnosis

A STUDY OF THE LÆVULOSE TOLERANCE TEST FOR HEPATIC EFFICIENCY.[*]

BY GORDON KING, F R C S. ENG, L R C P. LOND,
LATE CHEMICAL PATHOLOGY ASSISTANT, HALE CLINICAL LABORATORY LONDON HOSPITAL

THE use of lævulose as a means of testing hepatic efficiency was first suggested by Strauss [1] in 1901. The original test depended upon the detection of lævulosuria after the oral administration of 100 g. of the sugar. Strauss concluded that the presence of lævulose in the urine indicated an impairment of the liver function. In 1912 Schrokauer [2] demonstrated that the administration of lævulose to a normal fasting subject caused little or no rise in the blood-sugar curve; cases of obvious disease of the liver, on the other hand, showed a definite rise. MacLean and de Wesselow [3] reaffirmed this discovery in their important work on sugar tolerance in 1920, when they stated that lævulose appeared to be the only sugar which gave no definite rise in the blood-sugar content after ingestion. Spence and Brett [4] gave an admirable description of the lævulose tolerance test in 1921 and concluded that it afforded a valuable means of estimating the actual degree of liver dysfunction. Covell,[5] Tallerman,[6] and other workers have confirmed these results. Still more recently Finkelstein and Dannenberg,[7] working in St Louis, have given their opinion as to the value of the test. Greene, Snell, and Walters [8] on the other hand, have concluded, in a recent survey of tests for hepatic function, that the clinical importance of the lævulose tolerance test is still undecided.

The present study is based upon an investigation of 53 cases and was undertaken with the view of determining the clinical value of the lævulose tolerance test in various types of liver disease.

Theoretical Basis of the Test.

It has been shown that the animal body has practically no tolerance for lævulose when it is perfused continuously into a superficial vein.[9] Almost the whole of the sugar thus introduced into the circulation is immediately excreted by the kidneys. When, however, lævulose is given by the mouth it is found that a considerable dose can be tolerated without giving rise either to a recognisable increase in the blood-sugar or to any marked degree of lævulosuria. In the former instance it is clear that owing to its direct access into the systemic circulation comparatively little of the lævulose can be subjected to the action of the liver. In the latter instance, however, all the lævulose which is absorbed from the intestine must first pass through the portal system to the liver before it can gain entrance to the systemic circulation. The natural interpretation of these facts is that the liver alone has the power of building up and storing lævulose. In fact, as Sir Humphry Rolleston has noted [10] lævulose is the only carbohydrate of which the metabolism cannot be carried on elsewhere in the body than in the liver. It may be stated in brief therefore that normally there is little or no rise in the blood-sugar curve following the ingestion of a given amount of lævulose.

The sequence of events is far different, however, in the case of gross liver disease, whether due to degeneration, atrophy, inflammation, or new growth. In these circumstances the liver cells are either partly destroyed or rendered individually less capable of function. They are therefore unable to deal efficiently with the lævulose after it is absorbed from the intestine. Consequently the sugar evades polymerisation and escapes from the portal into the systemic circulation, there giving rise to a marked increase in the blood-sugar content, the extent and duration of which may be regarded as indicative of the degree of liver damage.

It is clear that three factors, apart from the activity of the liver, will tend to influence the height attained by this blood-sugar curve:—

In the first place the rate of absorption from the gut must be considered. In cases where chronic inflammation or atrophy of the mucous surfaces is present the rate of absorption will be correspondingly slow, and the concentration of lævulose in the blood at any given time will be relatively lower than in cases with healthy mucous membrane.

Secondly, the pancreas has a very intimate connexion with certain stages in the metabolism of sugars in the animal body. Clearly, then, an anomalous result might be obtained by exhibiting lævulose in a case of pancreatic deficiency. This possibility must be excluded, if need be, by separately determining the glucose tolerance. A reaction to lævulose can only be taken as abnormal if there is no evidence pointing to pancreatic disorder.

Finally, the rate of elimination of the sugar from the blood must have a definite reaction upon the height of the lævulose curve. Elimination is mainly effected by the kidneys, and in some cases is much more rapid than in others. In passing, it may be noted that the threshold for lævulose is considerably lower than that for glucose. Lævulose can be detected in the urine after quite small degrees of rise above the fasting level of blood-sugar.

It is important that these three factors should be borne in mind in interpreting the results of the lævulose tolerance test.

Technique of the Test.

For routine work, the custom has been to order the patient to starve from midnight. Eight or nine hours later a sample of blood is taken for the purpose of estimating the fasting sugar level. To an average adult a dose of 45 g. of lævulose, dissolved in 100 c cm. of water, is then administered by mouth, and samples of blood are collected thereafter at accurate half-hourly intervals for two hours. Specimens of urine are also taken before the test and at each hour during its progress. Finally, the percentage of sugar is estimated in each of the samples of blood and a curve is plotted indicating the result in graphic form. The specimens of urine are also examined both qualitatively and quantitatively for lævulose, but in practice this procedure has been found to be of little additional value when once the blood-sugar curve is known.

The blood-sugar estimations have all been performed on 0.2 c cm. of blood taken from one of the fingers into a finely graduated pipette. The method of estimation employed has been the colorimetric one described in 1919 by Folin and Wu,[11] the necessary volumetric modifications being made to allow for the smaller amount of blood utilised. For practical purposes this method has been found quite as accurate as that involving venepuncture—and certainly much less trying to the patient. It is to be noted that the sugar estimations include the sugar normal to the blood, together with the superadded lævulose content. It is impossible to estimate lævulose separately in the blood—neither would any useful purpose be served in so doing, for since the reducing power of lævulose so very nearly corresponds with that of glucose the estimation of the combined sugar value of the blood is for all ordinary purposes sufficiently accurate.

It has not been found necessary to make any fine adjustment of the dose of lævulose to the body weight. In the majority of adult cases a routine dose of 45 g. as suggested by Tallerman,[6] was found satisfactory.

Results in Normal Cases.

Before attempting to apply the test to known instances of liver disease it was decided to make observations on a series of normal cases. Accordingly, ten such cases were investigated and the results

---

[*] This investigation was carried out under the auspices of the Eliza Ann Alston Research benefaction.

estimation alone, but as surely as the content is high—i e, not less than 180 mg—it points strongly to an obstructive jaundice In only one other condition are such high cholesterol figures obtained, and that is the nephrosis of Epstein Cholesterol, like the bile salts, passes in a circle through the blood—>liver—>ducts—>intestine—>blood, with a variable loss in the fæces In obstructive jaundice this route is impeded, and there is a consequent damming back in the circulation, producing a high figure The hypercholesterolæmia that is supposed to be present in cases of cholecystitis has not been confirmed—in fact, the gall-bladder can be full of pathological conditions, the patient can be persistently fed with cholesterol containing substances, as long as the ducts remain patent, little increase can be made out in the cholesterol content of the systemic circulation

Some cholesterol estimations obtained in various diseases are here appended —

		mg per cent
H R	Gall stones and cystitis	111
E W	Jaundice—carcinoma pancreas	250
A. L	Cirrhosis of liver	95
F G	Enlarged liver without icterus (cirrhosis)	78
R B	Syphilitic liver	105
M U	Obstructive jaundice	305
H H	Cirrhosis	109
M C	Malignant jaundice (obstructive)	212
M M	Toxic jaundice	140
M N	Cirrhosis	83
B M	Nephrosis (28/10/25)	517
	(6/11/25)	444
	(24/11/25)	240
C T	Diabetes	127
T T	Diabetes—diabetic coma	210
J S	Obstructive jaundice	340
P A	Pernicious anæmia	97
A	Obstructive jaundice	333
	Addison's disease	78
	Carc breast, sec liver obstructive jaundice	308
A B	Cirrhosis	131
D T	Acholuric jaundice	145

It can be seen, therefore, that in cases of jaundice, if the cholesterol is above 180 mg per cent, it points to an obstructive type

Van den Bergh Reaction—The utility of this reaction has not proved to be proportional to the initial reputation it gained Although extremely disappointing in the laboratory, and being definite only when there are at the same time definite diagnostic facts equally well observed at the bedside, it has nevertheless brought into prominence Aschoff's work on the reticulo-endothelial system It has also brought to light the extrahepatic type of jaundice, and has made it possible to estimate the bilirubin content of the serum—an estimation undoubtedly of great value Success has not resulted when an attempt has been made to differentiate the various types of jaundice by the intensity of colour and time of appearance The only satisfaction that can be obtained is whether the van den Bergh is direct or not—to be able to diagnose and divide into any further groups is highly hypothetical The use of caffeine sodium salicylate to enhance the colour of the diazo-reaction has also yielded little profit Further studies are now being carried out on the constitution of the bile pigments in various types of sera, and an attempt is being made to ascertain the difference between the bilirubin that has passed through the hepatic cell and that which has not passed, a difference which becomes almost doubtful, except for a possible difference in quantity or a difference intimately related to the duration of the jaundice It is known already how easily bilirubin changes to biliverdin—how the marked changes in colour occur when the reaction is changed—how even the reaction (alkali or acid) of stomach contents that are tinged with bile can be judged by the green or blue colour of the contents It is possible that similar colour changes—but quite intermediate—occur in bilirubin in sera in various conditions and during various stages of the jaundice These or other facts may explain the uncertain colour changes observed in alcoholic extractions that have been advocated as differentiating facts, but which have so frequently proved valueless Except therefore for the estimation of the degree of bilirubinæmia, little proof has been forthcoming that the van den Bergh reaction adds any more information in the diagnosis of jaundiced cases It is indeed manifest to an observer who has attempted any work on the condition of jaundice how delicate the eye sense is, and how little is gained by any further laboratory investigations of the pigment by the van den Bergh reaction

Fouchet Test—This test is always regarded by all who have experience of it to be highly valuable It was introduced to demonstrate the presence or absence of a pathological degree of bilirubinæmia It is supposed to show an amount of 1 to 60,000, but it promises to be even more delicate

Bile salts in the urine indicate the jaundice to be of obstructive origin Bile salts are sometimes found to be present when no icterus is present—dissociated jaundice of the French—this is little understood

Urobilin—The presence or absence of urobilin in the urine has proved to be of great value, if present it generally supports the diagnosis of a jaundice to be due to some toxic state, in mechanical cases it is always negative

A *diastase* content in the urine of over 50 units assists in attributing the cause of the icterus to a primary pancreatic lesion

Example of icterus due to obstruction:—

Blood van den Bergh reaction direct immediate cholesterol content 220 mg per cent, galactose tolerance test 100, 110, 121, 109, 94 Urine urine sugar less than 1 g, bile salts and pigments positive, urobilin negative

Example of an icterus toxic in character (catarrhal jaundice)—Blood van den Bergh reaction indirect, cholesterol content 126 mg per cent, galactose tolerance test 94, 120, 160, 145, 126 Urine sugar content in three hours 5 5 g, bile salts negative, bile pigments and urobilin positive

Example of an extrahepatic jaundice (pernicious anæmia)—Blood van den Bergh reaction indirect, cholesterol content 97 mg per cent galactose tolerance test 94, 112, 108, 99, 81 Urine No galactosuria, bile salts, bile pigments, and urobilin negative

The three cases detailed are examples of the three great divisions of jaundice, and the galactose test yields positive results in the second group only

The two factors to note in the galactose tolerance test are the maximum difference obtained in the blood sugar level and the amount in grammes of reducing substance present in the urine A difference of over 30 mg in blood-sugar indicates some positive degree, frequently as much as 160 mg difference is obtained The second factor is the amount in grammes lost out of the 40 g ingested, and which must always be estimated Any amount of over 2 g proves a decided hepatic deficiency As the threshold for galactose is less than that for glucose, sugar appears in the urine with a blood-sugar value that is often not higher than 130 mg, so that one sees quite frequently a small degree of galactosuria even in health after the administration of 40 g In small children it is customary to modify the dose, but no rigid standard has been adopted

Summarising the pathological states, it is seen that in *obstructive jaundice* the galactose test is negative, but the van den Bergh reaction is direct, the cholesterol content is high, and bile salts are present in the urine, while in *toxic and infective jaundice* (including the hepatitis called catarrhal jaundice) and in any other lesion of the hepatic cell the following are the salient features a difference of blood-sugar far exceeding 30 mg per cent, a loss of over 2 g in the urine, a normal cholesterol content, a van den Bergh reaction which is indefinite with generally bile pigments only in the urine, and lastly, an urobilin reaction which is strong in degree

In *extrahepatic jaundice* the main features are on the negative side—a negative galactose test, absence of urobilin in the urine, and the normal cholesterol content being the main aids in diagnosis

A STUDY OF THE LÆVULOSE TOLERANCE TEST FOR HEPATIC EFFICIENCY *

BY GORDON KING, F R C S ENG, L R C P LOND,
LATE CHEMICAL PATHOLOGY ASSISTANT, HALE CLINICAL LABORATORY, LONDON HOSPITAL

THE use of lævulose as a means of testing hepatic efficiency was first suggested by Strauss[1] in 1901 The original test depended upon the detection of lævulosuria after the oral administration of 100 g of the sugar Strauss concluded that the presence of lævulose in the urine indicated an impairment of the liver function In 1912 Schirokauer[2] demonstrated that the administration of lævulose to a normal fasting subject caused little or no rise in the blood-sugar curve, cases of obvious disease of the liver, on the other hand, showed a definite rise MacLean and de Wesselow[3] reaffirmed this discovery in their important work on sugar tolerance in 1920, when they stated that lævulose appeared to be the only sugar which gave no definite rise in the blood-sugar content after ingestion Spence and Brett[4] gave an admirable description of the lævulose tolerance test in 1921 and concluded that it afforded a valuable means of estimating the actual degree of liver dysfunction Covell,[5] Tallerman,[6] and other workers have confirmed these results Still more recently, Finkelstein and Dannenberg,[7] working in St Louis, have given their opinion as to the value of the test Greene, Snell, and Walters,[8] on the other hand, have concluded, in a recent survey of tests for hepatic function, that the clinical importance of the lævulose tolerance test is still undecided

The present study is based upon an investigation of 53 cases and was undertaken with the view of determining the clinical value of the lævulose tolerance test in various types of liver disease

Theoretical Basis of the Test

It has been shown that the animal body has practically no tolerance for lævulose when it is perfused continuously into a superficial vein[9] Almost the whole of the sugar thus introduced into the circulation is immediately excreted by the kidneys When, however, lævulose is given by the mouth it is found that a considerable dose can be tolerated without giving rise either to a recognisable increase in the blood-sugar or to any marked degree of lævulosuria In the former instance it is clear that, owing to its direct access into the systemic circulation, comparatively little of the lævulose can be subjected to the action of the liver In the latter instance, however, all the lævulose which is absorbed from the intestine must first pass through the portal system to the liver before it can gain entrance to the systemic circulation The natural interpretation of these facts is that the liver alone has the power of building up and storing lævulose In fact, as Sir Humphry Rolleston has noted[10] lævulose is the only carbohydrate of which the metabolism cannot be carried on elsewhere in the body than in the liver It may be stated in brief, therefore, that normally there is little or no rise in the blood-sugar curve following the ingestion of a given amount of lævulose

The sequence of events is far different, however, in the case of gross liver disease, whether due to degeneration, atrophy, inflammation, or new growth In these circumstances the liver cells are either partly destroyed or rendered individually less capable of function They are therefore unable to deal efficiently with the lævulose after it is absorbed from the intestine Consequently, the sugar evades polymerisation and escapes from the portal into the systemic circulation, there giving rise to a marked increase in the blood-sugar content, the extent and duration of which may be regarded as indicative of the degree of liver damage

It is clear that three factors, apart from the activity of the liver, will tend to influence the height attained by this blood-sugar curve —

In the first place the rate of absorption from the gut must be considered In cases where chronic inflammation or atrophy of the mucous surfaces is present, the rate of absorption will be correspondingly slow, and the concentration of lævulose in the blood at any given time will be relatively lower than in cases with healthy mucous membrane

Secondly, the pancreas has a very intimate connexion with certain stages in the metabolism of sugars in the animal body. Clearly, then, an anomalous result might be obtained by exhibiting lævulose in a case of pancreatic deficiency This possibility must be excluded, if need be, by separately determining the glucose tolerance A reaction to lævulose can only be taken as abnormal if there is no evidence pointing to pancreatic disorder.

Finally, the rate of elimination of the sugar from the blood must have a definite reaction upon the height of the lævulose curve Elimination is mainly effected by the kidneys, and in some cases is much more rapid than in others In passing, it may be noted that the threshold for lævulose is considerably lower than that for glucose Lævulose can be detected in the urine after quite small degrees of rise above the fasting level of blood-sugar

It is important that these three factors should be borne in mind in interpreting the results of the lævulose tolerance test.

Technique of the Test

For routine work, the custom has been to order the patient to starve from midnight Eight or nine hours later a sample of blood is taken for the purpose of estimating the fasting sugar level To an average adult a dose of 45 g of lævulose, dissolved in 100 c cm of water, is then administered by mouth, and samples of blood are collected thereafter at accurate half-hourly intervals for two hours Specimens of urine are also taken before the test and at each hour during its progress Finally, the percentage of sugar is estimated in each of the samples of blood and a curve is plotted indicating the result in graphic form The specimens of urine are also examined both qualitatively and quantitatively for lævulose, but in practice this procedure has been found to be of little additional value when once the blood-sugar curve is known

The blood-sugar estimations have all been performed on 0 2 c cm of blood taken from one of the fingers into a finely graduated pipette The method of estimation employed has been the colorimetric one described in 1919 by Folin and Wu,[11] the necessary volumetric modifications being made to allow for the smaller amount of blood utilised For practical purposes this method has been found quite as accurate as that involving venepuncture—and certainly much less trying to the patient It is to be noted that the sugar estimations include the sugar normal to the blood, together with the superadded lævulose content It is impossible to estimate lævulose separately in the blood—neither would any useful purpose be served in so doing, for since the reducing power of lævulose so very nearly corresponds with that of glucose, the estimation of the combined sugar value of the blood is for all ordinary purposes sufficiently accurate

It has not been found necessary to make any fine adjustment of the dose of lævulose to the body weight In the majority of adult cases a *routine* dose of 45 g, as suggested by Tallerman,[6] was found satisfactory

Results in Normal Cases

Before attempting to apply the test to known instances of liver disease it was decided to make observations on a series of normal cases Accordingly, ten such cases were investigated, and the results are recorded in Table I All the cases were apparently normal, healthy individuals and they volunteered readily for the test

---

* This investigation was carried out under the auspices of the Eliza Ann Alston Research benefaction

TABLE I —*Series of Normal Cases*

No	Sex	Age	Blood sugar %					Height of rise
			Before	In ½ hr	In 1 hr	In 1½ hr	In 2 hr	mg
1	M	35	0·091	0·100	0·100	0·099	0·098	9
2	M	23	0·080	0·087	0·086	0·083	0·080	7

Average =			0·096	0·104	0·104	0·099	0·096	8

It will be noticed that in each case, after the administration of lævulose, there is a slight rise in the blood-sugar curve To facilitate reference, the height above the fasting level of the peak of the curve is expressed in the final column of the table as milligrammes of sugar per 100 c cm of blood Within an hour and a half or two hours there is almost invariably a return to the fasting level Cases 1 and 5 are the only exceptions to this, and in these the variation is so small as to be within the limits of experimental error In Case 3 considerable muscular work was undertaken during the second hour of the test, thus explaining a drop of the blood-sugar below the original fasting level In five of the cases no lævulose whatever could be detected in the urine during the test In the remaining five (Nos 1, 2 5 7, and 9) there was very slight reduction of Fehling's solution and a faintly positive Seliwanoff reaction This demonstrates the remarkably low renal threshold for lævulose

The results of all these cases have been coordinated together to form an average normal curve, a reproduction of which is given in Chart 1 This curve represents a rise of 8 mg above the fasting level It will be taken as expressing the reaction to lævulose of a normal fasting individual and will be referred to later in considering certain abnormal instances The fasting level of the blood-sugar varies considerably in different individuals—and even in the same individual at different times In estimating the lævulose tolerance the important factor to determine is, not so much the highest actual percentage of sugar present in the blood at any one time during the test, as the height of rise of the blood-sugar curve above the fasting level

Results in Abnormal Cases

These results are expressed in tabular form in Table II According to the height and duration of the curves obtained, the degrees of impairment of the liver function have been assigned as slight, moderate, marked, severe, and extreme In almost every case a parallel determination was made of the bilirubin content of the serum according to the method suggested by van den Bergh [12] and described by McNee [13] [14] This was of special interest in showing a definite degree of latent jaundice in many of the cases in which there was no jaundice clinically

The cases may be considered in various groups

1 *Portal Cirrhosis*—Twelve instances of this disease were investigated (Nos 11–22) In every case the lævulose curve reached an abnormal height, the maximum being usually obtained one and a half hours after the commencement of the test In no case was there a return to the fasting level by the end of the second hour A definite degree of jaundice (often not evident clinically) was also demonstrated in most of the cases by the bilirubin content of the serum Case 18 was a very early cirrhosis of the liver discovered at operation for another condition The curve is not very high, but it is interesting in that it continues definitely to rise at the end of the second hour There was no clinical evidence of cirrhosis in this patient Case 20 is of interest as showing the highest curve obtained in any patient of the series The patient was suffering from cirrhosis and perihepatitis ascites constantly recurred and he had been tapped 69 times when the test was performed The result is shown graphically in Chart 2

2 *Syphilitic Cirrhosis of Liver*—There was abundant evidence of this condition in Case 23 It will be seen that the test indicated a marked impairment of the liver function There were 3 6 units of bilirubin in the serum, as compared with 0 4 units in the normal subject

3 *Splenomegalic Cirrhosis*—A high degree of lævulose intolerance was exhibited in Case 24, death occurred a few months later Cases 25, 26, and 27 also showed varying degrees of liver inefficiency

4 *Malignant Disease*—Several instances of carcinoma of the biliary passages, pancreas, and stomach were investigated (Cases 28–39) In Case 28 the diagnosis of catarrhal jaundice was originally made There was a painless onset of jaundice and a smooth enlargement of the liver The lævulose intolerance was marked and the bilirubin content of the blood was high (27 units) A fortnight later the lævulose tolerance test was repeated and a slightly more abnormal result obtained (see Table II) Meanwhile, the bilirubin content of the serum had progressed to 54 units A provisional diagnosis of carcinoma of the head of the pancreas was then made and a few days later this was confirmed by the appearance of nodules of secondary growth on the surface of the liver Post mortem the liver was riddled with secondaries Other cases also showed diminished lævulose tolerance and in those instances which came to post mortem the liver was found to be invaded by masses of secondary carcinoma In Case 35 the gall bladder was found at operation to be full of purulent material This element of infection no doubt partly accounted for the extreme degree of liver inefficiency denoted by the test In cases of carcinoma of the stomach it seems probable that a useful application of the test would be to determine the presence of secondary deposits in the liver (Case 37) An unnecessary laparotomy might be avoided if the lævulose tolerance test denoted a marked degree of liver impairment

5 *Catarrhal Jaundice*—Case 40 is one of great interest The patient, a well-developed man of 33, was recovering from an attack of influenza for which he had been treated at home A week before admission to the hospital he complained of malaise and slight shivering attacks Two days before admission he lost all taste for food, vomited once, and began to experience a heavy feeling in the upper abdomen On admission he was slightly jaundiced and the urine contained bile The bowels had not been open for two days There were no enlarged glands and the liver and spleen were not palpable The jaundice increased for a week and then began to improve A week later the jaundice recurred, but from that time there was gradual improvement A month later the patient was discharged with only a faint remaining trace of jaundice The lævulose tolerance was determined just after the acute stage of the attack and again after recovery The results are expressed in Chart 3 There seems to be definite impairment of the function of the liver at the height of the disease which passes off as recovery takes place If catarrhal jaundice is pathologically an obstructive inflammation of the common bile duct with consequent retention of bile, one would not necessarily expect any lessening of the activity of the liver cells in metabolising lævulose—but such is the case It seems at least probable therefore that catarrhal jaundice is due

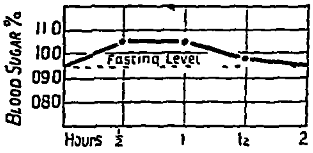

CHART 1 —Average normal curve

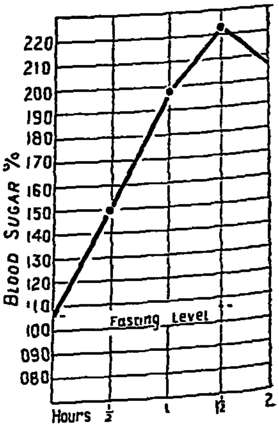

CHART 2 (Case 20) —Severe impairment

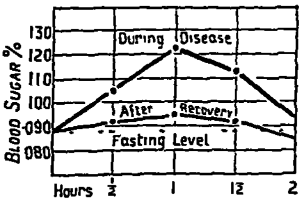

CHART 3 —Catarrhal jaundice

to a mild infection of the liver itself and is not dependent entirely upon an obstructive cholangitis

6 *Acute Cholecystitis* —An acute infective process in the gall-bladder seems to have a secondary influence upon the functioning power of the hepatic parenchyma In Case 41 a considerable impairment of the liver efficiency is indicated

7 *Chronic Cholecystitis* —This condition, on the other hand, has little or no adverse influence on the liver Case 42 shows a curve which approaches the normal In this case it was ascertained that a small, thickened gall-bladder, filled with stones, was present

8 *Acute Cholangitis* —These cases show diminished liver efficiency, probably due to back-spread of the infection Case 44 is interesting from this point of view The patient was a female, aged 34, for 15 years there had been symptoms of chronic cholecystitis, together with a history of two attacks of gall-stone colic A large chronically inflamed gall-bladder full of stones was removed, and the patient was discharged to a convalescent home A few weeks later she returned with pyrexia, rigors, and night sweats The rigors continued in the ward, jaundice developed there was bile in the urine, and the fæces were pale and bulky Dullness appeared at the base of the right lung, and the liver dullness showed signs of enlargement Either subphrenic abscess or cholangitis was suspected. Blood cultures were sterile, there was no leucocytosis, and no fluid or pus was obtained on needling in the region of the right base There was marked diminution of the lævulose tolerance (see Chart 4A) Cholangitis was accordingly diagnosed and the patient was treated with urotropine There was immediate improvement the temperature settled, and the jaundice began to clear Later the patient was transferred home with no pyrexia but slight jaundice When last seen the jaundice was slowly increasing (probably the result of some stenosis of the common bile-duct) but the temperature remained normal and the general condition was very satisfactory At this date the lævulose tolerance was normal (see Chart 4B) In this instance the lævulose tolerance test was of considerable diagnostic importance.

9 *Arsenical Jaundice* —It is known that arsenical poisoning affects the liver more gravely, perhaps, than any other organ Consequently, it was not surprising to find that there was an extreme degree of liver damage in two cases in which jaundice developed after the recent injection of an arsenical compound Both cases were being treated for syphilis Both recovered (Nos 46 and 47)

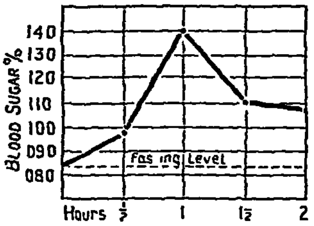

CHART 4 A —Acute cholangitis (during attack)

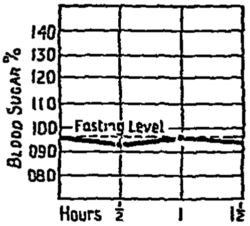

CHART 4 B —Acute cholangitis (recovery)

10 *Cardiac Failure* —Observations were made on three such cases In all of them (Nos 48–50) there was definite enlargement of the liver Only very slightly abnormal results were obtained in two cases In the other no abnormality could be detected Each case showed a definite degree of hyperbilirubinæmia

11 *Anomalous Cases* —There was only one anomalous case in the series In this there was extreme distension of the abdomen and it was impossible to tell whether this was due to free fluid or to the presence of a cyst. Cirrhosis with ascites, ovarian cyst, and hydatid cyst were all suggested as possible diagnoses The lævulose tolerance was diminished and this seemed to point to the diagnosis of cirrhosis At laparotomy a huge multilocular ovarian cyst was discovered The liver was extremely compressed

TABLE II —*Series of Abnormal Cases*

Clinical Value of the Test

A test for hepatic efficiency may be useful as an aid to diagnosis, as a means of controlling treatment and as a factor in prognosis

1 *As an Aid to Diagnosis* —In many cases the diagnosis is often clinically obvious before an opportunity for performing the lævulose tolerance test is offered In these instances the test is only useful inasmuch as it affords a definite index of the impairment of liver function In certain cases, however, the test may be of great value in settling a doubtful diagnosis The case of acute cholangitis quoted above is an example of this Two other cases will now be quoted in which the test was an important diagnostic factor.

Case 52 —Male, aged 58, dock labourer The patient was in hospital nine years previously with a history of abdominal pain but no vomiting At that time the liver was slightly enlarged The test-meal showed no free HCl and diminished total acidity A diagnosis was made of chronic gastritis, (?) hepatic cirrhosis Eighteen months before readmission there was a return of dyspeptic symptoms accompanied by occasional vomiting Later there was pain in the upper and lower abdomen accompanied by vomiting There was no hæmatemesis or melæna, the appetite was fair, but there was some loss of weight There was no previous history of any serious illness The patient was a moderate smoker and drinker On examination he was of healthy appearance, but somewhat neurotic in temperament The heart and lungs were normal The liver was not palpable but was slightly enlarged to percussion, no other abnormality was noticed Rectal examination showed nothing abnormal The test-meal showed no free HCl and diminished total acidity Wassermann reaction negative Radiological examination showed no evidence of any organic lesion of the stomach, pylorus, or duodenum The lævulose tolerance test was normal The possibility of hepatic cirrhosis was thus ruled out (See Chart 5) The final diagnosis was chronic gastritis

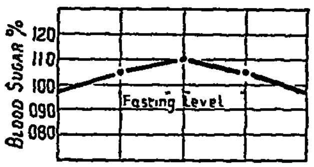

Chart 5 —Chronic gastritis

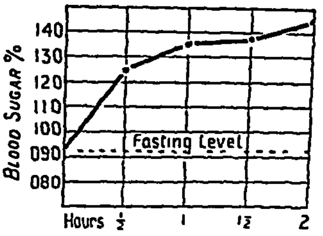

Chart 6 —Hepatic cirrhosis

Case 53 —Male, aged 58, costermonger The patient was quite well until a month before admission He then complained of pain in the upper abdomen, it was present every day, was not affected by food, and showed no radiation For a week before admission there was retching and some vomiting The day before admission he vomited blood twice There was no previous history of hæmatemesis or melæna The appetite was good, but there was slight loss of weight There was no previous history of any serious illness The patient was a non-smoker, but drank beer moderately

On examination he was a well built man but rather pale The heart and lungs were normal The abdomen was well covered but not distended, there was slight epigastric tenderness, the liver was enlarged three fingers-breadth below the costal margin The spleen was not palpable, there was no ascites Rectal examination showed nothing abnormal Blood examination showed a moderate degree of secondary anæmia The Wassermann reaction was negative The test-meal showed no free HCl and diminished total acidity Radiological examination showed no evidence of any organic lesion The lævulose tolerance was much diminished, and on this evidence a diagnosis of hepatic cirrhosis was made (See Chart 6)

In both these cases it may fairly be claimed that the lævulose tolerance test was one of the most important factors in reaching the diagnosis

2 *As a Means of Controlling Treatment* —Two circumstances will be mentioned in which the lævulose tolerance test might be of service in controlling treatment In cases where carcinoma of the stomach is diagnosed the question at once arises as to the operability of the condition Secondary deposits in the liver are a definite contra-indication to operation and these cannot always be excluded on clinical grounds In a case of undoubted carcinoma of the stomach the demonstration of a high lævulose curve would seem to point unquestionably to the presence of secondaries in the liver—and therefore to the inadvisability of laparotomy Again, in the administration of toxic drugs such as the arsenical compounds, the lævulose tolerance test might furnish valuable information as to the condition of the liver It is known that liver damage may occur or may be suspected even in the absence of jaundice In these cases the lævulose tolerance test would undoubtedly be of assistance and might prove of value in determining the dosage of the drug to be employed

3 *As a Guide to Prognosis* —The test is of value in this direction in that it furnishes a definite and scientific indication of the actual degree of liver damage

Conclusions

1 In a series of 53 cases the lævulose tolerance test for hepatic efficiency has shown consistent results

2 In ten normal cases the average rise of the blood-sugar curve above the fasting level after a dose of 45 g of lævulose by mouth was 8 mg per 100 c cm of blood Normally there was a return to the fasting level within one and a half or two hours

3 In cases of disease of the liver there was a definitely atypical reaction to a dose of lævulose The blood-sugar curve was abnormally high and maintained, the peak of the curve being reached about one and a half hours after the commencement of the test There was no return to the fasting level at the end of two hours The height and duration of the rise in the blood-sugar was in proportion to the degree of liver damage

4. The test is therefore of considerable value as an index of the functional capacity of the liver

5 In certain cases the test may be of considerable practical value as an aid to diagnosis, as a means of controlling treatment, and as a guide to prognosis.

Finally, the writer wishes to express his thanks to the physicians and surgeons of the London Hospital who have permitted their cases to undergo investigation, and to Dr P N Panton and Dr J R Marrack for their kind help and suggestions

Amalgamation of Bristol Hospitals —It has been decided that the Bristol Royal Hospital for Sick Children shall in future be worked in conjunction with the Bristol Royal Infirmary, and the professional staff amalgamated

Prince of Wales's General Hospital —This hospital at Tottenham, which, with its home of recovery at Nazeing, has 220 beds, is seriously in need of an extension of its out-patient department, which has not been enlarged since the time when it treated only one-third of the present number of patients The well-to-do population of the district has been replaced by a working class one, with grave results to the income

TWENTY-FOUR CASES OF RINGWORM OF THE SCALP TREATED BY THALLIUM EPILATION

BY G. B. DOWLING, M.D., M.R.C.P. LOND.,
DERMATOLOGIST, WEST LONDON HOSPITAL; ASSISTANT PHYSICIAN, ST JOHN'S HOSPITAL FOR SKIN DISEASES; PHYSICIAN, SKIN DEPARTMENT, MILLER GENERAL HOSPITAL;

AND

R. KELMAN, F.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, MILLER GENERAL HOSPITAL.

THE following brief account of a number of cases of tinea tonsurans treated by means of thallium epilation may be of some general interest. The method is so simple that it is not improbable that this treatment will replace to some extent the more commonly used Röntgen ray epilation.

The action of thallium acetate in producing epilation has been well known for many years, and R. Sabouraud about 30 years ago used the drug for this purpose in the treatment of scalp ringworm. As a result of his experience, however, he concluded that the therapeutic use of thallium was unsafe. Perhaps he used unnecessarily large doses. At all events it was given up.

The credit for placing the treatment on a sound practical basis belongs to A. Buschke, who by means of experimental work on animals carried out by himself at first and later in collaboration with Bruno Peiser and others[1] over a number of years succeeded in determining the exact dose of thallium acetate per kg. of body-weight which is required to produce epilation of the scalp. In the first place they point out the obvious disadvantages of X ray epilation, particularly in very young children—namely, that unless an exact epilatory dose be given, one of two things will happen: with imperfect technique portions of the scalp may receive too small a dose, epilation will not be complete, and the ringworm will not be cured; with an overdose, however slight, more or less permanent cicatricial alopecia may result. Further, they point to the not infrequent temporary damage to the skin following X ray irradiation. It is particularly difficult, of course, to epilate children under 3 years of age, for such very young children will not usually keep still for the time that is necessary for the epilation dose.

The advantages of making use of the elective action of thallium acetate in producing epilation were obvious, but a dose had to be found that would be non-toxic and yet effective. So after Sabouraud's therapeutic failures Buschke, and afterwards Buschke in collaboration with Peiser, undertook the experimental work over a period of 20 years which succeeded eventually in establishing the precise dose required and the best method of administration. On the basis of their experiments R. E. Cicero and others in Mexico made practical tests of the use of thallium on a large number of children suffering from ringworm of the scalp; a batch of 345 children were all treated successfully by this means, and equal success was reported in the treatment of a further group of 200 children. Reference is further made to groups of 104 and 40 children treated in Italy, all with success.

Reports of complications by some who have used the method are referred to in these papers, but these have been rare and slight in nature, consisting of slight albuminuria, joint pains, headache, and vomiting. Buschke suggests that these cases may have received too large a dose, and he states that he has himself never observed the smallest ill-effect.

The actual dose of thallium acetate required was established by Buschke to be 8 mg. per kg. of body-weight. Some have used 8–9 mg. per kg. of body-weight. A single dose is given by mouth in sweetened water. The hair begins to loosen in six to eight days, and complete epilation has taken place by the nineteenth day. Buschke also tried the combined effect of thallium and X ray epilation, using 4 mg. of thallium per kg. and 1/3 H.E.D. X rays. The result was prompt and satisfactory epilation without injury or complication of any sort. Toxic effects have been observed as the result of giving a second dose of thallium; but Buschke thinks that the second dose must have been given too soon. He considers that two and a half months is a necessary period to allow if the first epilation has failed.

Report of Cases.

A very few words will suffice to deal with our own results. We have simply followed Buschke's method of administering thallium acetate in sweetened water, giving 8 mg. per kg. of body-weight in some cases, and *8.5 or 9 mg. in others.*

We have dealt with 24 cases altogether. At first they were kept under observation for 24 to 48 hours. Later we concluded that this early observation was unnecessary and simply instructed the parents to keep the children in bed for a day. However, as will be pointed out later, confinement to bed during the whole period of treatment may be more desirable. As albuminuria may be a complication of thallium treatment, it is evident that its use in a case suffering from any renal affection is contra-indicated. A preliminary urinalysis has therefore been made in each case. Epilation has been satisfactory in every case treated with 8.5 and 9 mg. per kg.; with 8 mg. epilation has been just short of complete in a few cases. Unfortunately, we have not yet been able to get the biologically standardised thallium acetate used by Buschke, but we intend to obtain this preparation if possible for future use.

The ages of our patients have varied from 2 to 12 years of age. It is hardly necessary to add that epilation of itself does not cure ringworm, and a fungicide ointment has of course been used in combination with the thallium treatment. We have found that the hair which begins to loosen after six to seven days falls rapidly at about the twelfth day, and by the nineteenth day epilation is complete except for some sparse unpigmented hairs of the lanugo type which are found particularly near the hair margin and which never fall. In a few cases it has been found that the infected stumps do not fall as readily as the normal hair, and it has been necessary to resort to other measures to extract them. The same difficulty arises in some cases treated by X ray epilation, and the usual method is to extract these stumps by means of strapping. The method successfully followed in two cases of the present series has been daily application for four days of liq. ferri perchlor. fort. This forms a crust which adheres to the affected areas, and when this is washed off the remaining hairs are extracted. The hair has begun to grow again almost immediately in the form of down. Unfortunately, we are not yet able to state from our own experience how long a period must elapse before full regrowth is established. Buschke, however, states that regrowth has never failed in any case and is usually fully established by three months from the commencement of treatment.

Toxic Effects.

While no toxic symptoms have been noted in the first week of treatment, these unfortunately have not been entirely absent in the second and third weeks. Headache has been observed in one case in the third week, and some loss of appetite and pains in the joints in five cases in the second and third weeks. The knees and feet have been chiefly affected, and in one case the fingers. These symptoms have been relieved by rest in bed. They have lasted for eight to ten days. Curiously, these toxic effects have only become evident in quite recently treated cases, and it appears possible that the explanation may partly lie in the fact that the same thallium preparation has been used for some six weeks, and may have deteriorated It seems therefore, clear that it will be advisable for the future to obtain a freshly made, biologically standardised, and absolutely pure preparation of thallium, in order that the smallest possible effective dose may be given, and to keep the patients in bed during the whole period of treatment

---

[1] A résumé of the experimental work carried out by these authors and of the therapeutic tests made by them and by others may be found in the Dermatologische Wochenschrift of July 3rd, 1926, and in a paper by the same authors in the Urologic and Cutaneous Review, August, 1926.

This treatment will clearly be especially useful (1) in cases where X ray epilation is undesirable or impracticable, as, for example, in children under 3 years of age (2) In cases for which X rays have already been used without success One case may be cited as an example of the latter class

A girl of 6, an Australian, came under observation 17 days from the time of writing She had been treated for ringworm of the scalp by X ray about four months before In this case there had been not only a severe inflammatory reaction as a result of the irradiation but epilation had partially failed, and the ringworm had persisted

The patient's mother had taken a passage to Australia and it was urgently necessary that she should sail in three weeks The child was given 8 5 mg per kg of body-weight immediately She has epilated successfully in 16 days In this case no toxic symptoms of any kind have occurred

It will be possible to report on a larger group of cases in the near future, including some in which thallium has been used to supplement partially epilatory doses of X ray

Clinical and Laboratory Notes.

A CASE OF

PNEUMOCOCCAL MENINGITIS,

WITH COMPLETE RECOVERY FOLLOWING SERUM TREATMENT

By Alan S Simpson, M B , B S Lond ,

HOUSE PHYSICIAN, BELGRAVE HOSPITAL FOR CHILDREN

In the July issue of the *Archives of Pediatrics*, 1926, two American writers, Ratnoff and Litvac, have described a case of pneumococcal meningitis treated with Morgenroth's optochin hydrochloride. They review the literature of the subject and give a mortality of 95 per cent , and they indicate the lines of treatment in eight reported cases of recovery recorded during the last decade Their patient, a girl aged 7½ years, was admitted with a provisional diagnosis of cerebro-spinal fever, she was given antimeningococcal serum, and after this, repeated injections of antipneumococcal serum followed by a course of injections of Morgenroth's optochin hydrochloride , recovery resulted

The following case is therefore of interest in that the patient, a boy of 5, recovered completely, receiving antimeningococcal serum and antipneumococcal serum only.

H S , a boy aged 4 years 11 months, was admitted to the Belgrave Hospital on July 4th, 1926

The history was that he was quite well up to the morning of July 2nd, when he came in from play complaining of headache and vomited , the headache and vomiting persisted until his admission He was one of a family of six, and had previously been in good health. There was no family history of tuberculosis

Examination on Admission —The boy lay curled up in bed on one side, with retracted head and abdomen Temperature 99 5° F , pulse 88 (irregular), respirations 24 He had labial herpes He was drowsy and irritable, and cried out when disturbed At times he lapsed into semi coma with a divergent strabismus , the pupils were equal and reacted to light , he had marked cervico dorsal rigidity and Kernig's sign was positive , Tache cerébrale was absent Reflexes abdominals brisk , knee-jerks sluggish , ankle-jerks present , plantars flexor No evidence of disease elsewhere

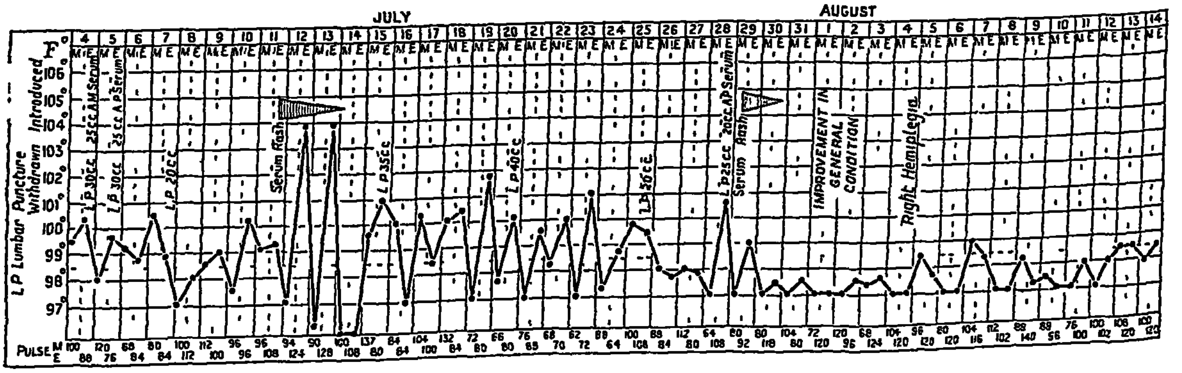
Lumbar puncture revealed a turbid fluid under increased pressure , a tentative diagnosis of cerebro spinal fever was made, and 25 c cm of antimeningococcal serum were given intrathecally, 30 c cm of C S F being previously withdrawn

The pathological report was 540 cells per c mm , polymorphs, 80 per cent ; lymphocytes, 20 per cent , total protein, 0 2 per cent , chlorides, 0 6 per cent No glucose Pneumococci were found in the direct smears and cultivated, but were not typed

On the next day (July 5th) 30 c cm C S F were withdrawn and replaced by 25 c cm of polyvalent antipneumococcal serum Two days later he showed marked improvement, the retraction was less and he began to take an interest in his surroundings , lumbar puncture showed the fluid to be much less turbid but no cell count was done Four days later (i e , on the eighth day after admission and his first dose of serum) he had headache, joint pains, a generalised urticarial rash, and was drowsy, but had no head retraction This serum reaction lasted over two days

Following the serum reaction his condition altered very little during the next 14 days , he complained of headache, ran an intermittent temperature, and had slight head retraction , marked constipation was a constant feature Three lumbar punctures were done during this period and the fluid remained turbid On July 28th a sensitising dose of antipneumococcal serum was given subcutaneously and later 25 c cm of C S F were withdrawn and 20 c.cm of antipneumococcal serum introduced An immediate reaction occurred on the following day The optic discs showed at this stage a slight papillœdema of the left disc In three or four days he began to show improvement, the temperature settled down, headache ceased, and head retraction became less On August 4th a right-sided hemiplegia was noticed, involving the arm and leg of that side , the reflexes on the right side were absent, including the abdominals, and the limbs were flaccid His general condition was good and he took an interest in his surroundings, but could not or would not speak at all A fortnight after the onset of the hemiplegia he suddenly began to speak, under emotional excitement his mother being present From then onwards his speech and hemiplegia made rapid improvement, and in three weeks he gained 6 lb in weight On Sept 10th he was discharged quite well, and "walked out" of hospital

Apparently this was a primary pneumococcal meningitis, though not very acute, in so far as the febrile symptoms were concerned There was never any evidence of a focus of infection in the ears, fauces,



Temperature chart of a case of pneumococcal meningitis with recovery or respiratory tract and the labial herpes was such as is frequently seen in pneumonia In a primary case mentioned by Dr. E Cautley in his 'Diseases of Children,' the boy, aged 9 months had an acute illness which ran a course like that of simple croupous pneumonia, the temperature falling by crisis on the tenth day and ending in recovery. The diagnosis was verified by lumbar puncture but no serum treatment was adopted An interesting feature of the above case is the right hemiplegia of flaccid type associated with an aphasia which cleared up synchronously.

I wish to thank Dr. Cautley for assistance and kind permission to publish this case

---

A CASE OF
'SONNE' DYSENTERY IN ENGLAND.

BY F H A CLAYTON MD MRCP.EDIN,
LECTURER IN BACTERIOLOGY UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

As a result of his investigation into the occurrence of dysentery in Denmark, Carl Sonne[1] described, in addition to the well-recognised Shiga and Flexner groups a third variety, found in mild cases, which differed from them both culturally and serologically The accuracy of his observations has since been confirmed by F d'Herelle[2] in France T Thjötta[3] in Norway, and H Oehnell in Sweden A similar organism has been studied in Australia by S W Patterson and F E Williams[4] and recently a considerable outbreak of illness due to it has been described in Aberdeen[5] but in England it had not been met with until H. A Channon[6] in 1925 obtained it from the fæces of a man who gave a history of previous dysentery in Egypt

The Present Case.

The patient a lady resident in a seaport town in Durham appears to have suffered for some time from intermittent attacks of abdominal pain and discomfort. The present exacerbation began early in September 1926 and was marked by considerable pain on the right side and symptoms sufficiently suggestive of appendicitis to call for a surgical opinion although operation was not considered advisable Frequent scanty motions containing blood and mucus and attended by tenesmus then troubled the patient and on Sept 8th a specimen of fæces was brought direct to the laboratory of the College of Medicine by a consultant physician of Newcastle-on-Tyne who had been called in The specimen arrived within an hour or two of its passage.

Under simple treatment the condition soon improved, and in a few days the patient was said to be practically well, and although she has apparently had one or two "threatenings" she has so far as is known had no further definite attack

Examination of the Stool.

Macroscopically the stool seemed to consist almost entirely of mucus and bright blood with a little greenish fæculent matter Films showed large numbers of polymorphonuclear cells some macrophages epithelial and red blood-cells and a few crystals but no cysts or amœbæ and but few organisms

From MacConkey plates, sown with washed flecks of mucus six out of a considerable number of clear white colonies were isolated and were found to give, after 24 hours' incubation the reactions of *Bacillus dysenteriæ* (Flexner) which were maintained for some six days At about the end of that time a distinct acidity which persisted became apparent in litmus-milk and this was followed by the slow production of acid in lactose and a day or two later in saccharose No indol could be demonstrated and agglutination against the Oxford sera for the five strains of *B dysenteriæ* (Flexner) proved entirely negative The patient's own serum was then obtained and agglutinated the organism isolated up to 1 in 125 a fact suggesting that infection had predated the present train of symptoms the serum failed however with the five Oxford Flexner emulsions to give more than a very doubtful trace with "Y"

Two strains of the 'Sonne' bacillus (Nos 268 and 269) were obtained from the National Collection of Type Cultures and were found to give precisely similar cultural reactions, the only difference being that acid appeared in lactose and saccharose a day or two earlier One cultural characteristic, of which no mention has been seen but which was noted with all three strains was the occurrence of lateral branchings in gelatin stabs

From one of the type Sonne strains (No 268) and from the organism isolated anti-sera were prepared in the usual manner. Neither appeared to possess great antigenic potency but no difficulty was experienced in producing, with dead organisms sera which would agglutinate 24-hour broth cultures up to 1 in 600 or 700 The agglutination is rather fine as was noted by Thjötta and is best seen with the Oxford dark-ground apparatus devised for the purpose Cross-agglutination experiments showed almost identical results with all three organisms except that type strain 268, even with its own serum, seemed slightly less agglutinable than the other two Cross-adsorption was equally conclusive as with each serum the heterologous as well as the homologous strain removed practically all the agglutinins for both

There seems no doubt therefore that this is the "Sonne" bacillus and inquiry was made as to any connexion with Aberdeen or the Scandinavian countries and whether there was any possibility that residents in the house, either visitors or domestics coming from these places might have filled the rôle of carrier No very definite information was obtained, but it was gathered that the patient herself, her husband—who had also suffered from abdominal symptoms—and an intimate friend had all, at an unspecified date been in Aberdeen

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY

AT a meeting of this Section held on Feb. 5th Dr DAN MCKENZIE the President, occupied the chair, and Dr E FARQUHAR BUZZARD contributed a paper (read in his absence by Mr T. B LAYTON) on the

Treatment of Traumatic Facial Palsy

The principles governing the treatment of all lesions affecting the lower motor neurones must, he said apply to lesions of the facial nerve, but the path of the nerve through the temporal bone, where trauma might be caused created difficulties which deserved attention In certain cases it was impossible to say whether the nerve had been completely divided or whether it had been lacerated bruised crushed, or merely exposed to inflammation in adjacent tissues Speaking generally a facial palsy, the result of a lesion of the nerve in its course through the temporal bone did not require operation and all that had to be considered was whether other measures would be likely to help recovery

There were two main groups of these cases of facial palsy, continued Dr. Buzzard In the first were cases in which the lesion did not cause reaction of degeneration and in which there was some return of function however slight within three weeks of the palsy commencing In these cases it was evident that the nerve's function had been only temporarily suspended Probably little help resulted from treatment in these cases, but gentle rubbing of the facial muscles and attempts to move the face somewhat helped restoration When inflammatory disease persisted there was a somewhat longer delay in recovery In the second group of cases reaction of degeneration was present three weeks from the commencement of the paralysis and only the passage of time would show whether recovery was possible. No evidence of it was seen for at least three or four months, and by no known means could regeneration be hastened Efforts should be devoted to preserving the nutrition and contractility of the muscles concerned and to preventing disfiguring contractions. It was desirable to use a simple apparatus designed to prevent the mouth being drawn over to the opposite has been used for some six weeks, and may have deteriorated It seems therefore, clear that it will be advisable for the future to obtain a freshly made, biologically standardised, and absolutely pure preparation of thallium, in order that the smallest possible effective dose may be given, and to keep the patients in bed during the whole period of treatment

This treatment will clearly be especially useful (1) in cases where X ray epilation is undesirable or impracticable, as, for example, in children under 3 years of age (2) In cases for which X rays have already been used without success One case may be cited as an example of the latter class

A girl of 6, an Australian, came under observation 17 days from the time of writing She had been treated for ringworm of the scalp by X ray about four months before In this case there had been not only a severe inflammatory reaction as a result of the irradiation but epilation had partially failed, and the ringworm had persisted

The patient's mother had taken a passage to Australia and it was urgently necessary that she should sail in three weeks The child was given 8 5 mg per kg of body-weight immediately She has epilated successfully in 10 days In this case no toxic symptoms of any kind have occurred

It will be possible to report on a larger group of cases in the near future, including some in which thallium has been used to supplement partially epilatory doses of X ray

Clinical and Laboratory Notes.

A CASE OF
PNEUMOCOCCAL MENINGITIS,
WITH COMPLETE RECOVERY FOLLOWING SERUM TREATMENT

By ALAN S SIMPSON, M B, B S LOND,
HOUSE PHYSICIAN, BELGRAVE HOSPITAL FOR CHILDREN

IN the July issue of the *Archives of Pediatrics*, 1926, two American writers, Ratnoff and Litvac, have described a case of pneumococcal meningitis treated with Morgenroth's optochin hydrochloride They review the literature of the subject and give a mortality of 95 per cent, and they indicate the lines of treatment in eight reported cases of recovery recorded during the last decade Their patient, a girl aged 7½ years, was admitted with a provisional diagnosis of cerebro-spinal fever, she was given antimeningococcal serum, and after this, repeated injections of antipneumococcal serum followed by a course of injections of Morgenroth's optochin hydrochloride, recovery resulted

The following case is therefore of interest in that the patient, a boy of 5, recovered completely, receiving antimeningococcal serum and antipneumococcal serum only.

H S, a boy aged 4 years 11 months, was admitted to the Belgrave Hospital on July 4th, 1926

The history was that he was quite well up to the morning of July 2nd, when he came in from play complaining of headache and vomited, the headache and vomiting persisted until his admission He was one of a family of six, and had previously been in good health There was no family history of tuberculosis

Examination on Admission—The boy lay curled up in bed on one side, with retracted head and abdomen Temperature 99 5°F, pulse 88 (irregular), respirations 24 He had labial herpes He was drowsy and irritable, and cried out when disturbed At times he lapsed into semi coma with a divergent strabismus, the pupils were equal and reacted to light, he had marked cervico dorsal rigidity and Kernig's sign was positive, Tache cerébrale was absent Reflexes abdominals brisk, knee-jerks sluggish ankle-jerks present, plantars flexor No evidence of disease elsewhere

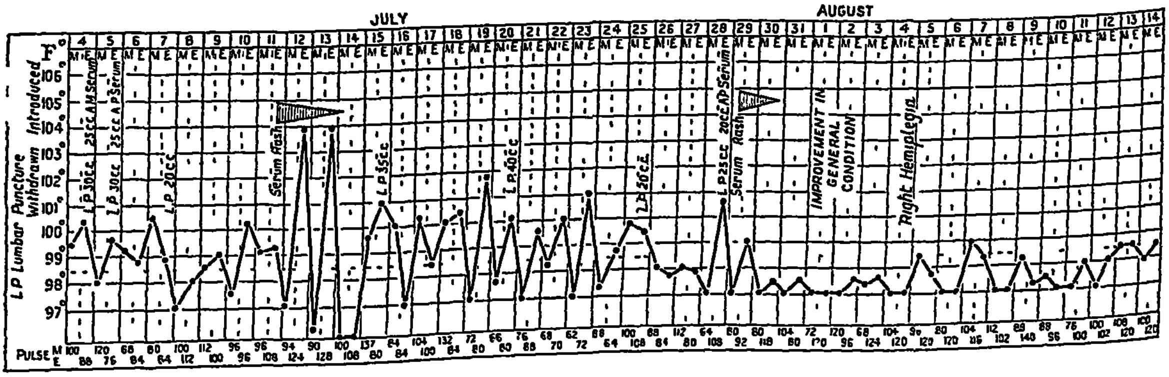
Lumbar puncture revealed a turbid fluid under increased pressure, a tentative diagnosis of cerebro spinal fever was made, and 25 c cm of antimeningococcal serum were given intrathecally, 30 c cm of C S F being previously withdrawn

The pathological report was 540 cells per c mm., polymorphs, 80 per cent, lymphocytes, 20 per cent, total protein, 0 2 per cent, chlorides, 0 6 per cent No glucose Pneumococci were found in the direct smears and cultivated, but were not typed

On the next day (July 5th) 30 c cm C S F were withdrawn and replaced by 25 c cm of polyvalent antipneumococcal serum Two days later he showed marked improvement, the retraction was less and he began to take an interest in his surroundings, lumbar puncture showed the fluid to be much less turbid but no cell count was done Four days later (i e, on the eighth day after admission and his first dose of serum) he had headache, joint pains, a generalised urticarial rash, and was drowsy, but had no head retraction. This serum reaction lasted over two days

Following the serum reaction his condition altered very little during the next 14 days, he complained of headache, ran an intermittent temperature, and had slight head retraction, marked constipation was a constant feature Three lumbar punctures were done during this period and the fluid remained turbid On July 28th a sensitising dose of antipneumococcal serum was given subcutaneously and later 25 c cm of C S F were withdrawn and 20 c cm of antipneumococcal serum introduced An immediate reaction occurred on the following day The optic discs showed at this stage a slight papillœdema of the left disc In three or four days he began to show improvement, the temperature settled down, headache ceased, and head retraction became less On August 4th a right-sided hemiplegia was noticed, involving the arm and leg of that side, the reflexes on the right side were absent, including the abdominals, and the limbs were flaccid His general condition was good and he took an interest in his surroundings, but could not or would not speak at all A fortnight after the onset of the hemiplegia he suddenly began to speak, under emotional excitement his mother being present From then onwards his speech and hemiplegia made rapid improvement, and in three weeks he gained 6 lb in weight On Sept 10th he was discharged quite well, and "walked out" of hospital

Apparently this was a primary pneumococcal meningitis, though not very acute, in so far as the febrile symptoms were concerned There was never any evidence of a focus of infection in the ears, fauces,



Temperature chart of a case of pneumococcal meningitis with recovery pyramidal tract—i.e., absent or diminished abdominal reflexes, increased tendon-jerks, and a plantar response which was either extensor or doubtful. The third sign, less constantly present, was of great value when found—namely, defect in the visual field owing to the optic radiation being involved. When abscess was suspected the visual fields should always be examined.

With cerebral abscess, went on Dr. Symonds, the cerebro-spinal fluid was clear and contained from 18 to 95 cells per c.mm., mostly lymphocytes. The chloride content was normal and sugar-reducing bodies were present. A preponderance of polymorphonuclear cells in the fluid, with diminution of chlorides and absence of sugar-reduction, usually indicated meningitis, and leakage into the ventricular system or the subarachnoid space.

In the course of formation of an abscess there must be a presuppurative stage of inflammation, and he suggested that arrest could be produced at this stage without pus formation being reached.

Discussion.

The PRESIDENT said that in the books it was stated that nystagmus was not noted in 70 per cent. of cases of cerebral abscess. It was sometimes very difficult to detect, especially in a stuporose patient. If the attention of such a patient could be directed to the same side as the lesion the eyeball would be seen to return slowly to the midline. When there was a discharge from the ear in cases of encephalitis lethargica it was apt to be assumed that cerebral abscess was present, and operation might be performed.

Sir JAMES DUNDAS-GRANT spoke of the importance of being able to recognise superficial abscess.

Mr. F. W. WATKYN-THOMAS described a case of abscess over the right lateral sinus, which was drained. Following the operation definite aphasia developed, this being the only case in which he had seen aphasia in such a condition. The patient died and the course of the infection could not be traced. At autopsy a definite depression was found over the anterior portion of the Sylvian fissure, over the foot of the Rolandic area, and extending to the frontal. In none of the kind of cases under discussion did there seem to be evidence of "crossed-deafness," or of pure word-deafness.

Mr. SCOTT emphasised the importance of withdrawing only a minimal quantity of cerebro-spinal fluid in these cases. In one case a surgeon withdrew two test-tubes full of fluid, and unconsciousness and arrest of breathing followed. In regard to aphasia, he preferred the term "naming amnesia." The patient should be asked to name quite a number of objects. Leucocytosis in the blood was important in distinguishing non-suppurative cases of localising encephalitis.

Mr. LESLIE POWELL pointed out the importance in a very sick man of doing the mastoid operation first and waiting a day or two before opening the abscess.

Sir WILLIAM MILLIGAN emphasised the value of Dr. Symonds's comments on non-suppurative encephalitis, which might be due to circumscribed serous meningitis.

Mr. JENKINS spoke particularly on the cases having a big accumulation in the subarachnoid space, which were often diagnosed as abscess of brain tissue.

Dr. SYMONDS replied.

SECTIONS OF OPHTHALMOLOGY AND NEUROLOGY.

A JOINT meeting of these Sections was held on Feb. 11th, under the chairmanship of Mr. ERNEST CLARKE, President of the Section of Ophthalmology. A discussion on the value of

Present Day Use of Treatment in the Late Stages of Ocular Syphilis

was opened by Mr. J. H. FISHER, who commented on the swing of the pendulum noticeable in the drug treatment of syphilis during the last two or three years. It had, unfortunately, become common to order grey powder in tablet form, so that it was passed undissolved, and to give iodide of potassium in minute doses of 3 or 5 gr. when at least 30 gr. were required. A more intimate association between ophthalmologist, physician, neurologist, and surgeon was desirable; not a few cases of enlarged glands, arthritis and bone disorders, previously diagnosed as tuberculous, would have been revealed as syphilitic by ophthalmoscopic examination. The efficacy of Donovan's solution, such drugs as atoxyl and soamin, and Ehrlich's discovery of salvarsan and neosalvarsan had caused the pendulum to reach an extreme. The conclusion of those qualified to judge, however, had been that the older drugs were still essential for the cure of the disease, and that the Wassermann reaction could only be a useful adjunct to the other means of diagnosis. Modern methods and modern drugs varied within wide limits, and every syphilologist appeared to have laid down his own course of treatment. The increased readiness of patients to seek treatment, the facilities for obtaining it, and its more efficient administration must not be forgotten in estimating the value of modern methods. A true comparison could only be made when properly organised statistics of late manifestations and syphilitic nervous diseases had been compiled.

Among the late manifestations of syphilis in the eye were iritis, scleritis, disseminated choroiditis, interstitial keratitis, and ophthalmoplegia; also diffuse neuro-retinitis with dust-like opacities in the vitreous. This last seemed to be less common than when the speaker had begun his work, and the improvement might well be the result of the more thorough and systematic treatment of the disease in its primary stage. The new injection treatment had been of great value in secondary syphilitic iritis, since the antidote was brought directly to the vascular iris by the blood stream. For the same reason it should be more efficient in preventing the lodgment of the spirochaete in the vascular choroid. Interstitial keratitis from acquired syphilis arose from 5 to 29 years after the primary infection, and never attacked the other eye. The manifestation in the cornea was always (1) deep invasion of the corneal layers with ciliary injection at the base of a tongue-shaped area of advancing haze, and (2) extension to deep vessels. Inunction with mercury had always cleared up the trouble, and the use of the eye was preserved if treatment were started early. In interstitial keratitis from inherited syphilis, however, no kind of treatment arrested or modified the disorder. It had been observed that treatment was of more use in cases where dense vascularisation of the cornea had occurred; if this were so the reason would be that the drug, since introduced intravenously, passed directly to the site of the inflammation. The reason why anti-syphilitic methods were so powerless in keratitis of inherited syphilis might be that the whole tissues of the cornea were impregnated with the spirochaete or its products from the time of conception, whereas in the acquired form the condition was only the chance lodgment of a single focus.

Neurological Disorders.

He was sure that it was possible to delay the advance of optic atrophy in tabes by a thorough course of mercurial treatment, particularly where a well-maintained field had been present when the patient first came under treatment. It must be remembered that many tabetics showed temporary diplopias which certainly cleared up under the older forms of treatment, but ophthalmoplegia dependent upon nuclear degeneration might also be limited by the early circulation of the antidote in all parts of the basal nerve stem. In the same way vascular disorders might be prevented, including aneurysms and sclerotic changes. Gummatous meningitis had always been amenable to the energetic administration of mercury and potassium iodide.

Dr. J. PURDON MARTIN dealt with the neurological symptoms of late ocular syphilis, which followed the side and the stretching of the muscles at the corner and upper border of the mouth Muscular nutrition and contractility could be preserved by massage and by the make and break of the galvanic current With the return of voluntary movement the best course was a re-education of the muscles in front of a mirror; other measures could now be suspended. Sometimes at this stage there ensued postparalytic contracture, with some permanent shortening of muscles, and a failure to control the facial expression properly occasionally with awkward results It was difficult to say during what interval massage and galvanism was advisable in the hope that regeneration of the nerve would occur; but usually, if there was no response to faradism at the end of six months, further massage and electricity seemed useless He had not yet had sufficient experience of anastomosis of the nerve to enable him to form a very definite opinion on it

Discussion

The PRESIDENT thought that the decision whether or not to carry out anastomosis could best be reached by considering the cause of the paralysis in the particular case Recovery was likely when the cause of the trouble was that the nerve had been struck by a blunt instrument But if during an operation the nerve was severed by a blow from the mallet or a sharp chisel it was difficult to know what would happen to it In most of the cases he believed recovery would follow if it was left alone Anastomosis was still in the experimental stage, and every effort should be made to perfect it, then, perhaps, dependable rules could be laid down At present even the most successful operation of anastomosis did not restore complete emotional expression

Mr A J. M WRIGHT and Mr SYDNEY SCOTT thought that six months was too short a time-limit for recovery, and Mr Scott referred to a case of his own in which restoration took place after three years.

Sir WILLIAM MILLIGAN remarked on the comparative rarity of postoperative facial paralysis in this country, which he considered was a tribute to the care mostly exercised in these operations. Sometimes injury to the facial nerve was due to the subsequent dressing, perhaps to packing too tightly, or to the use of caustics He considered that six months was too short a time-limit for recovery, and had seen a patient completely recover after two years of paralysis He had never seen such complete recovery after anastomosis as that which nature could bring about unaided

Mr. E WATSON-WILLIAMS alluded to the prognostic significance of the time at which facial paralysis came on. If it was manifest at or immediately after the operation the paralysis was likely to be more serious than when two or three days elapsed between the operation and the beginning of the paralysis He had especially noted the difference after labyrinthectomies, and for that reason hesitated before doing the operation The profession owed a debt of gratitude to Sir Charles Ballance for his work on the anastomosis of nerves, and for pointing out what nerves could be spared Mr Watson-Williams had twice divided the glossopharyngeal nerve, and in neither case had the patient suffered any inconvenience That particular nerve, strange to say, would take on a motor function

Sir JAMES PURVES-STEWART said that he did not think that trauma in the middle ear, whether surgical, accidental, or suppurative, was amenable to anastomosis, because the trouble was in the Fallopian aqueduct The cases in which operative intervention was justifiable were those in which the nerve was healthy down to the stylomastoid foramen It was of no use to anastomose a sensory nerve to the distal end of the facial nerve With regard to the selection of the nerve for anastomosis, the hypoglossal was more easy to identify and deal with than the glossopharyngeal, and the spinal accessory was easier still

Mr G J JENKINS referred to a case in which anastomosis of the descendens hypoglossi gave a fairly satisfactory result four years after facial paralysis began

Sir JAMES DUNDAS-GRANT spoke of recovery of traumatic facial paralysis after digital massage, also after mild galvanic stimulation by the anodal pole of the battery

Mr M E VLASTO said that after the performance of anastomosis there was a loss of the former tone of the muscle The comparative infrequency of traumatic facial paralysis in this country he attributed to the greater operative timidity of British in comparison with continental and American surgeons

Mr LIONEL COLLEDGE said that in the cases which were going to recover there was usually evidence of improvement within four months Recovery was improbable after the lapse of six months though it occasionally occurred In doing anastomosis it was very important to use the whole nerve, end-to side anastomosis was not likely to restore dissociated movement

Dr C P SYMONDS said that a possible explanation of some of these cases of long-delayed recovery was that there was a functional perpetuation of what had been an organic disability If a patient were merely a passive agent and the doctor was content with massage and electricity there was a danger that when regeneration occurred he would not exploit it properly Exercises before a mirror were very valuable

Dr SYMONDS then read a paper on

Diagnosis and Localisation of Cerebral Abscess,

confining his attention to abscess arising from suppuration in the ear and situated in the dural membrane In the early stages of abscess formation, he said, usual symptoms were fever, rapid pulse, malaise, and anorexia, suppurative encephalitis and severe headache sometimes followed, with vomiting and drowsiness with the increased cranial pressure Commonly the suppurative process became localised and an abscess cavity with tough walls was found There was then no diffuse encephalitis The headache was increased by stooping and coughing Severe headache, vomiting, and drowsiness, with slowing of the pulse, showed that obstruction had occurred to the outflow from the ventricles, with internal hydrocephalus, and the result might be fatal In the early stages it was usually necessary to rely for the diagnosis on the signs of local damage caused by the abscess

The localising signs of cerebral abscess could be considered under (1) cerebellar, (2) left temporal (3) right temporal In the first of these, suboccipital headache was important, but later it was usually bifrontal or general Generally the abscess was deep in the lateral lobe, and then there was incoördination of movement in the limbs on the same side The simplest method of examination was that by the nose-finger test, the examiner's finger being shifted each time, and the response of the patient being required quickly Another valuable sign was nystagmus, there being a tendency for the eyes to swing away from the side on which the cerebellar lesion was situated In abscess of the left temporal lobe (in a right-handed person) the valuable localising sign was aphasia This sign might not be present when the abscess was far forward in the lobe, but it was an early sign when the abscess was in the middle or the posterior third Though a patient suffered from definite aphasia he might yet be able to converse without apparent difficulty The appropriate method must be used to detect this The patient should be asked to name quite a number of articles There were only three signs of value of right-sided temporal abscess in a right-handed person One was slight weakness on the opposite side of the face, shown on smiling less evident when the patient is asked to show his teeth The second group of signs were those of pressure on the

General Discussion

Colonel L. W. **Harrison** said that if mortality were a guide to morbidity it seemed probable that congenital syphilis would become rarer. The statistics of the Registrar-General showed a marked drop between 1917 and 1924. He thought the treatment of interstitial keratitis in congenital cases well worth while though disappointing. At Rochester Row good results had followed subconjunctival injections of salvarsanised serum. For gummatous manifestations he believed that potassium iodide was very valuable to clear up the mess after the spirochætal activity had been stopped by a spirochætocidal remedy. He was sure that the omission of mercury or bismuth from the treatment of early cases increased the incidence of ophthalmoplegias later. By far the majority of the cases were in patients who had been treated by arsenobenzol alone. He had compared the results at the St. Thomas's Hospital centre with those of the Johns Hopkins Clinic. At the former mercury and bismuth were combined with arsenobenzol and there had been no case of cranial nerve palsy. At the latter they had used "606" alternately with courses of mercury inunction, and out of 2500 cases had had 58 neuro-recurrences, including cranial nerve palsies. Arsenobenzol gave good results when given subcutaneously or intramuscularly; in fact by these routes the tissues were given more time to form that derivative of the drug which was spirochætocidal. He pleaded for perseverance in treatment; 20 injections of both drugs should be given after the Wassermann reaction became negative.

Dr. N. **Pines** described his successful results in interstitial keratitis with the intravenous injection of sodium iodide in large doses. The cornea cleared up rapidly and the patients never showed signs of iodism.

Dr. **Gordon Holmes** did not agree that the optic atrophy of general paralysis of the insane and tabes must necessarily lead to blindness; many cases preserved their vision for years, especially under treatment. The essential lesion was an interstitial syphilitic process associated with primary degeneration of a certain number of nerve-fibres—i.e., a cellular infiltration in the nerve, usually along the pia and especially marked about the region of the optic foramen. In this case the prognosis should not be so bad. In 1919 he had selected 20 cases and treated half of them with arsenic or arsenic and mercury together, and half with mercury alone. The result had left no doubt that arsenic was relatively ineffective and that mercury in full physiological doses up to mild salivation, was necessary to get results. He did not agree that self-inunction was useless. Bismuth was more useful in the ocular palsies, especially those of tabes. From the neurologist's point of view it was a pity that Ehrlich had ever discovered the arsenical preparations.

Mr. **Lindsay Rea** showed slides illustrating a number of conditions including interstitial keratitis, exudate in the vitreous, papillœdema, and gumma at the side of the cornea, which had cleared up under N.A.B. He would not admit that nothing could be done: the case should be treated early with N.A.B. followed up by mercury and iodides. The Wassermann reaction must not dominate the treatment, and the Lange gold reaction must be taken. The constitutional condition of the patient must not be forgotten and treatment must be continued for years in small doses. Big doses did harm.

The **President** remarked on the importance of teaching the public that they must continue treatment.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

On Feb. 1st Dr. **James Orr** gave an address on the later views of Sir James Mackenzie on the

Nature of Cardiac Action,

with particular reference to the phenomena of heart-block. Mackenzie's work, he said, had been the subject of adverse criticism, mainly on the ground that it was purely speculative. Mackenzie was a speculative thinker, but the views he expressed latterly were based upon prolonged clinical observation. In view of this criticism it was important to examine his position critically in the light of modern experimental research. This position was distinctive in its conception of the Purkinje system of the heart—the nodes and bundle—as the regulating and controlling structure of the organ. The cardiac muscle only contracted in response to stimuli reaching it from this source, and conduction in the bundle was attained, not by the passage of an impulse along a conducting structure, as that term was generally understood, but by successive stimulation of contiguous cells in the bundle, each one discharging an individual impulse. For this reason Mackenzie described the nodes and bundle as the "genetic" system of the heart.

Recent experimental work, said Dr. Orr, had led to general agreement that the S.-A. (sino-auricular) node was normally responsible for initiating the cardiac contraction. As regards the spread of the excitation wave through the auricle, the balance of evidence, having regard to direction and spread and rate of transmission, was greatly in favour of a spread through the auricular muscle. A spread between the S.-A. and A.-V. (auriculo-ventricular) nodes by means of a distinctive path had not been demonstrated, though an experiment by Mines showing the persistence of electrocardiographic deflections after the abolition of muscular contraction, was suggestive.

In the ventricle there was no doubt, Dr. Orr continued, that the spread of excitation was accomplished by means of the bundle and its ramifications. The question centred upon the means by which this spread was accomplished, whether by simple conduction or by cell stimulation. Experimental observation made it clear that the A.-V. node could not be regarded as a simple conductor, and that it acted as a centre for the discharge of impulses. The phenomena of the nodal extrasystole and of reversed heart-block demonstrated this conclusively. With regard to the bundle, question arose as to the source of the ventricular beats in complete auriculo-ventricular dissociation. That there was no set ventricular rate was shown by the fact that in a single individual who was subject to complete heart-block, the ventricular rate varied at different times from 30 to 45 per minute. The electrocardiogram in conditions of complete heart-block showed that the excitation wave entered the ventricle supra-ventricularly. It presumably had its origin either in the A.-V. node or in the supra-ventricular part of the bundle, immediately peripheral to the lesion. This view was accepted by many experimental observers and the trend of recent work seemed to be in the direction of regarding the whole Purkinje system as essentially a stimulus-producing structure. Mackenzie's conception of the Purkinje system as a genetic structure afforded a complete and consistent explanation of the phenomena observed experimentally and clinically. The only alternative was to regard it as a conducting mechanism which, in certain circumstances, acquired the capacity of producing stimuli.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting of this Institution held on Feb. 3rd Mr. **Frank Jeans** read a paper entitled

Some Problems of Urological Surgery.

Dealing with mobile kidney, he said that very few cases needed operation and those that did, if diagnosed early by pyelography, needed division of the so-called aberrant renal artery and no nephropexy. Most of the real cures of symptoms by nephropexy could have been brought about by division of this artery, a much more physiological operation than the fixation of an organ which Providence had decided should be fairly mobile. He did not believe that mere mobility of a kidney—unless it was liable to obstruction—e.g., same classification as syphilis of the central nervous system into the three divisions of (1) parenchymatous disease of the brain or spinal cord, (2) syphilis of the cerebral adventitia, and (3) the paracentral or tabetic type of neurosyphilis Parenchymatous cerebral syphilis showed itself in the Argyll Robertson pupil and isolated pupillary palsies and irregularities. It resisted chemical methods, but often yielded to the new malarial treatment, in so far as the nerve elements were still capable of recovery Many general paralytics treated in this way showed great ocular improvement The commonest symptoms of adventitial syphilis were papillœdema and palsies due to increased intracranial pressure, which would clear up under early specific treatment Delay, however, allowed the papillœdema and its exudate to increase, and the exudate to organise and become permanent, resulting in a greater atrophy of the nerve-fibres as the œdema subsided

The nervous damage in tabetic or paracentral syphilis, he said, appeared in structures outside the central nervous system in close contact with the meninges and cerebro-spinal fluid, such as the posterior nerve roots and ganglia and the optic nerve In oculomotor palsies the affected nerve was almost certainly involved in this way at the meningeal level The results of treatment depended on its institution as early as possible, or at any rate before the nerve was completely paralysed According to Stargardt, the nerve suffered from the infiltration of its sheath by minute gummata, the chief point of invasion being where the nerve passed through the dura This infiltration generally yielded to iodides and mercury, and unless the nerve-fibres had been killed they would recover Similarly, even if they had been completely interrupted and had started to degenerate, new fibres would grow down on relief of the infiltration and recovery take place in a few months If, however, organised exudate permanently interrupted the path of the fibres, or the ocular muscles degenerated, recovery was impossible The rule in orthopædics was that a muscle from which the nerve-supply had been temporarily cut off should be placed in a position of complete relaxation, as if it were stretched it degenerated quickly. Paralysed ocular muscles, however, were unfortunately in continuous tension, and tenotomy of the opposing muscles was contra-indicated for various reasons Existing drugs were potent enough, and the need was for some way of freeing a passage for the new nerve-fibres and of maintaining the integrity of the paralysed muscle for some months Optic atrophy resisted specific treatment because of the vulnerability and lack of recuperative power of the optic nerve It was not often recognised early enough If, however, it were taken in time, energetic chemical treatment could produce fair results Novarsenobillon in doses of not more than 0 6 g was the drug of election at present, and if more potent remedies were invented the results would be improved Finally, Dr Martin warned his hearers against the snare of the negative Wassermann

The Value of Rest in Optic Atrophy

SIR **ARNOLD LAWSON** said that his war experience of primary optic atrophy had brought his pessimism on that subject to a head Cure was practically hopeless Organic arsenic was in some cases absolutely harmful, for mercury he had nothing but contempt, and iodides in large doses had but a very limited use and were unsatisfactory In primary optic atrophy the degeneration was not the secondary result of an active inflammation, which might itself be cured, so checking the degeneration; the cause was irremediable and we could only hope to arrest the progress of the condition He would like to know the true value of the Wassermann reaction in clinical syphilis Out of 109 men admitted to St Dunstan's with primary optic atrophy 62 had had a positive Wassermann and 20 had been negative, 27 were so bad that treatment was impossible Nearly all had been through military hospitals and had intensive treatment, but there was no trace of difference between those who had been treated and those who had not, unless the former were worse All had gone the same way He suggested that there might be a hope for these cases in skilful, scientifically-applied rest, both general and local, administered in sanatoriums on the lines followed in the treatment of tuberculosis

Dr A **FEILING** spoke of his personal experience, as a neurologist, of affections of the optic nerve and ophthalmoplegias The meningo vascular types tended on the whole to occur earlier and to be more or less amenable to treatment, the primary or parenchymatous degenerative forms were late and very resistant to treatment Occasionally an optic neuritis would occur without any other signs or symptoms in the nervous system, and the Wassermann reaction might be negative, but the cerebro-spinal fluid would show the characteristic changes He quoted a case in which treatment had restored the function Much more common was syphilitic optic atrophy He thought that the isolated form, not associated with obvious signs of general paralysis of the insane or tabes, ran a more benign course He had followed a number of cases for periods up to five years, and six of them at least had not progressed after treatment There was a very sharp distinction between nuclear palsies and those associated with isolated muscles and due to syphilitic meningitis In the former treatment was seldom any use, in the latter it would cure, at all events for the time being Internal ophthalmoplegias were very common and occurred without other clinical evidence of syphilis. They could be regarded as syphilitic scars and might take all varieties of form He had never seen the syphilitic Argyll Robertson pupil disappear as the result of treatment, though pupillary reactions might get brisker The Argyll Robertson pupil of other conditions, such as encephalitis and chronic alcoholism, might disappear with treatment He had never seen miosis alter at all He agreed that the cerebro-spinal Wassermann should always be taken in ocular syphilis The treatment he used was intravenous administration of novarsenobillon at weekly intervals, with a month's remission after six doses He had seen one case where decided deterioration in vision occurred after tryparsamide, and many other cases had been reported, but he knew of no signs of visual defect following other kinds of arsenical administration.

The Syphilologist's Point of View

Mr S H **BROWNING** laid emphasis on the importance of treatment by a syphilologist He had treated many hundreds of cases of interstitial keratitis with the new methods of treatment—salvarsan, neosalvarsan, and bismuth—though nearly always combined with mercury He was convinced that they did better with intensive antisyphilitic treatment than without it, and some of his results had been almost dramatic He referred to the work of Carwell and Derby[1] in Massachusetts This work had definitely settled the question in favour of treatment For tabes the treatment resolved itself into a judicious blend of the old and the new, and the individual patient must be considered For the hospital case treatment must involve as little pain and incapacity as possible, or the patient would disappear when the symptoms disapppeared For those who could afford it, however, the Aachen treatment—mercury inunction, baths, mineral waters, &c —was undoubtedly the best, preferably at Aachen He regarded self-inunction as futile For the last few years he had replaced mercury by metallic bismuth with excellent results The treatment of a tabetic involved far more than chemicals The doctor should advise on small matters like clothes, which made all the difference between pain and rest for the patient There was little to be said for the newer remedies in the ideal treatment of late syphilis, but they had their place if the treatment was to be a compromise with the patient's circumstances metabolism of the carbohydrates The section on respiration is one of the finest modern accounts of this system to be found in any students' text-book, and in this new edition practically all the recent work on the subject finds a place The reader naturally turns soon to the section on insulin where he hopes to obtain some glimpses into the history of its discovery, which, as is universally known, was made in Prof Macleod's own laboratories Greater detail on the earlier experiments of Banting and Best would have been appreciated The whole section summarising the work on insulin is well planned, but a fuller description of the chemical properties of the substance and of its distribution in the body would have added greatly to the value of the account For instance, the fact that insulin can be recovered from the tissues of depancreatised dogs is merely mentioned and no reference at all is made to its presence in the tissues of patients dying of diabetes mellitus The section dealing with the adrenal glands is rather disappointing The historical review is somewhat sketchy; from it the student would gather that the earliest workers in this field were Takamine and Abel, and an account of the classical investigations of the older workers, such as Henle, Kruckenberg, and Holme, would have made the section more complete Moreover, the absence of any description of the method of synthesis of adrenalin is to be regretted In the section on the internal secretions of the ovary the important work of Herrmann and Frankel and Allen and Doisy on the œstrus producing hormone prepared from the follicular fluid is ignored C R Harington's observations on the constitution and synthesis of thyroxin may not have reached Toronto until after this work was in the press In a future edition it might be better to replace the illustration on page 27 by one where the E M F is measured by means of an ionisation potentiometer, such as is now on the market

---

[1] THE LANCET, 1925, ii, 764

This volume has already proved to be of the greatest value in providing the student with a reliable account of the application of physiology and biochemistry to medicine, and the new edition is likely to be as popular as its predecessors

DENTAL MATERIA MEDICA

Modern Dental Materia Medica, Pharmacology and Therapeutics Fifth edition By J P BUCKLEY, Ph G, D D S, F A C D, Professor of Materia Medica, Pharmacology, and Therapeutics, Chicago College of Dental Surgery London. William Heinemann (Medical Books), Ltd 1926 Pp 586 30s

THIS book is divided into two parts, a section dealing with materia medica and pharmacology, and a section on practical dental therapeutics The first section follows the usual lines of general text-books on materia medica containing accounts of the different types of pharmaceutical preparations, mode of administration, dosage, and so forth It appears to us that this section of the book might have been reduced without impairing its value, since it contains much that is of little moment to the dental student On the other hand, certain drugs of importance in dentistry, notably adrenalin, might well have received fuller treatment. We find no mention either of the strength of the adrenalin which it is advisable to use in local analgesia or the symptoms resulting from an overdose, still less of the remedies appropriate to such a catastrophe. In the section on hæmostatics only the local application of the preparations derived from fibrin ferments and thromboplastic substances is described, though they are much more potent when injected Oil of turpentine, a very old remedy of considerable efficacy, is not mentioned as a hæmostatic. The account of gum tragacanth omits its most important property in dentistry—namely, its power of increasing the retention of dentures when sprinkled on the surface applied to the palate We might quote many other examples in which the treatment of drugs of especial use in dentistry appears to be too brief, while many sedatives and cathartics only occasionally used in dentistry are fully considered

The second section on practical dental therapeutics comprises half the book and is the more interesting part, containing much valuable matter We do not always agree with the author, but on the whole his account of the part played by various drugs in such conditions as pyorrhœa, pulpitis, and neuralgia is sound He refers to two preparations of his own—of one of them the exact formula is not given Some enthusiasm may be allowed to an inventor, but Prof Buckley praises its efficacy in terms that might have been left to others Those who allow for the author's prejudices, and skip the padding, will find in this book some useful accounts of the part played by drugs in the treatment of various dental conditions

INTRODUCTION TO EXPERIMENTAL EMBRYOLOGY.

By G R DE BEER, Fellow of Merton and Jenkinson Memorial Lecturer Oxford Oxford · The Clarendon Press 1926 Pp 148 7*s* 6*d*

WE welcome this book Records of experiments, replete with a variety of turgid detail, are scattered throughout the extensive scientific literature of the world, and the bearings of any individual experiment or set of experiments on questions at issue are not always apparent except to those who are working in the same field Others whose activities are affected in greater or less degree by the results obtained or suggested, frequently have not the time to follow out the ramifications of experiments, and will be grateful for the short accounts of results given in Dr de Beer's little book It excludes experimental work on the sexual glands and characteristics, and does not profess to give more than enough to throw a little light, in the words of the author, on the essentials of the problems of animal development Connexion between the various subjects is well preserved.

Short chapters on regeneration and tissue culture are included, and a list of the numerous papers and books utilised completes a useful little work

TELEOLOGY

Man not a Machine By EUGENIO RIGNANO With a preface by HANS DRIESCH London: Kegan Paul, Trench, Trubner and Co 1926. Pp 77 2*s* 6*d*

Prof Henry Fairfield Osborn says in a recent book, " If I have made a single contribution to biology which I feel confident is permanent, it is the profession *that living Nature is purposive* " There was a time when a man might have been burnt at the Darwinian stake for less, all that has happened to Prof Osborn has been to be made a foreign member of the Royal Society And it is significant that almost all the serious attempts which are made nowadays to explain life and evolution come to similar conclusions Allowing that heretics are always likely to be more vocal than the orthodox, it is surprising how few books are written to support Jacques Loeb in his view that life is a chemico-physical system, though there are, of course, a great number of papers in biological periodicals which make that implicit assumption. The present slender volume by the editor of "Scientia," where a symposium on vitalism and mechanism has smouldered for a long time, makes no pretence to be a formal treatise; it is more like a manual of devotion containing a brief statement of the faith that the fundamental characteristic common to all vital phenomena is that they present a purposive, teleological, or finalistic aspect It will strengthen those who think like the author, and will give them much food for thought and some fresh points of view We would commend it especially to pathologists, who live in a peculiarly illustrative atmosphere, which indeed Prof Rignano realises, though when he notices the specificity of antitoxins (p 38) he makes a bad mistake in his facts by an extra artery—produced symptoms attributable to the kidney and to hydronephrosis

Speaking of renal tuberculosis Mr Jeans laid emphasis on its insidious onset, quoting cases in which it followed post-parturient pyelitis, gonorrhœa, and the persistence of a bullet in or near the kidney In these cases the patients had owed their lives to the fact that their doctors had suspected tubercle in time to save them by nephrectomy An important cystoscopic sign diagnostic of early tuberculosis of one kidney was the rebound, at an acute angle, of the colouring fluid used as an indicator This proved a thickening of the lower edge of the ureteric outlet, and was very valuable as being the earliest sign which could be detected Early diagnosis by cystoscopy was very desirable, all his private patients who had had nephrectomy were well, but he had to think hard to recall hospital patients who were still alive for they came for treatment when the condition was already bilateral

In prostatectomy, said Mr Jeans he favoured the so-called blind operation, as against the long incision at sight with the patient in the Trendelenburg position Men with high blood pressure did not stand the Trendelenburg position well, the operation took 20 minutes longer, and complications were therefore commoner

Prof JOHN HAY and Dr WALLACE JONES submitted a paper on

Trauma Responsible for Auricular Fibrillation

from the medico-legal standpoint The trend of their communication was to show that trauma or physical strain was sometimes the exciting factor in the production of auricular fibrillation The disability might occur as the result of a man's employment, and in such cases the employers would be liable They reported five cases, in one of which fibrillation was caused by a severe electric shock A man sitting on an electric crane accidentally placed his forehead against the live terminals of the crane, receiving 250 volts of direct current, before the accident he had been perfectly healthy but after it the auricles continued to fibrillate until the fibrillation was broken by quinidine In the other four cases three of the patients were men in whom ordinary clinical examination had not revealed any cardiac disease or damage and who had not had any subjective manifestation of cardiac inadequacy before the onset of fibrillation In all three fibrillation occurred as the result of sudden definite physical effort In the fifth case the heart had not been sound, there had been evidence of slight aortic regurgitation, and the electrocardiogram had shown a right bundle lesion Up to the time of the accident, however, this patient had carried on comfortably with his ordinary occupation Then when lifting a heavy weight on to a roof he had suddenly "felt something give in his chest" Fibrillation had started at that time and had persisted, and the patient had been unable to resume his occupation The medico-legal significance of these facts was of considerable practical importance

---

ACTION AGAINST A DENTIST—At Liverpool Assizes on Feb 7th damages were claimed against a dental surgeon of Chorley for personal injuries alleged to have been caused to the plaintiff, a 13 year-old girl, when she was 8 years old, by his assistant For the plaintiff it was stated that in May, 1922, the girl had some teeth taken out by the dentist's assistant so badly and roughly that her face swelled and she had to be treated daily for seven or eight weeks Ultimately she was taken into Chorley Hospital, where a piece of decayed bone, which had loosened from the jaw, was removed Later several operations were performed at Pendlebury Hospital at Manchester The girl's face was now lop-sided, and she bore permanent scars from the operations It was alleged that when the teeth were extracted the plaintiff's jaw splintered, that it became septic, and that this caused her to suffer from necrosis of the jaw Dr Rigby, of Chorley, stated that when he saw the girl four months after the extraction there was nothing to lead him to an opinion that the teeth had not been properly extracted Evidence to somewhat similar effect was given by Mr Gilbert Warburton, senior surgeon at Pendlebury Hospital Mr Justice Wright entered judgment for the defendant

Reviews and Notices of Books.

SURGERY A HUNDRED YEARS AGO

Extracts from the Diary of Dr C B Tilanus, afterwards Professor of Surgery at the University of Amsterdam Edited by Prof H T DEELMAN, Professor of Pathology at the University of Groningen Translated from the Dutch by JOSEPH BLES London Geoffrey Bles Pp 156 6s

THE origin of this diary was a tour made in 1818 by C B Tilanus and two friends, J C Broers and P J de Fremery, who had all three just taken their medical degree at the University of Utrecht and had decided to visit the various clinics in Belgium, France, and Germany before settling down They must have employed their time well, for in after life we find them as professors at the Universities of Amsterdam, Leyden, and Utrecht respectively A sketch of their careers is given in the introduction to this book by Dr Delprat of Amsterdam They first visited the hospital at Louvain, where Tilanus notes that, "they use here *acetus morphii* even up to 4 gram (60–62 grains) but they do not appear to have as yet obtained any satisfactory results from it It was prescribed to-day in small doses in a case of persistent vomiting" It looks as though there were some error in either the diary itself, the transcription, or the translation, for if the maximum dose of morphia acetate—presuming that acetus does mean acetate—was really "even up to 4 gram" we do not wonder that the results were not satisfactory From Louvain the three young doctors went to Paris, where for some six months they studied in the clinics of Dupuytren, Boyer, and Larrey, also noting the practice of other surgeons The operations, although brilliantly performed, generally ended in death from sepsis What strikes a modern observer even more than the dexterity of the surgeon is the heroic endurance of the patients An account is given of the extirpation of most of the lower jaw concerning which Tilanus remarks, "the operation was difficult and took a considerable time", the patient died on the nineteenth day after the operation From Paris they went on to Germany, where in Heidelberg they met Chelius and Nagele, and at Cassel they were shown over the museum by Prof Matsko, to whom they gave a tip of two thalers for his trouble, which, Tilanus remarks, "his Excellency did not refuse" At Halle, with which town the diary ends, they interviewed Sprengel and Meckel, the former told them that his chief interest was gardening The diary is well worth reading as a simple but intelligent account of interesting people and events.

The medical profession owes a debt of gratitude to Mr J L Tilanus for having placed his father's diary at the disposition of Prof Deelman and to Prof Deelman for having made an excellent little book out of the diary

PHYSIOLOGY AND BIOCHEMISTRY IN MODERN MEDICINE

Fifth edition By J J R MACLEOD, M B., LL D, D Sc, F R S, Professor of Physiology in the University of Toronto, Canada, formerly Professor of Physiology in the Western Reserve University, Cleveland, Ohio London. Henry Kimpton 1926 Pp 1054 42s

THE appearance of the fifth edition of this well-known text-book will be welcomed The general character of the book remains unchanged, but some of the sections have been brought fully up to date Thus the portion dealing with the physiology of the neuromuscular system has been expanded and rewritten by Dr A C Redfield A section on the physiology of the special senses has been added by Dr J M D Olmsted, and many new points have been included on the physiological and chemical aspects of blood, respiration, ductless glands, and the

THE LANCET.

HUNTER AND LISTER

Sir Berkeley Moynihan's public career as resident of the Royal College of Surgeons of ngland may be said to have been inaugurated when he delivered the Hunterian Oration on Monday ast, and the date being the 199th anniversary of Hunter's birth, falling in the centenary anniversary f the birth of Lister, a comparison of the ideals and erformances of these two outstanding figures made splendid subject for a Hunterian Oration, and ne to which the President did eloquent justice Hunter and Lister are international surgeons who vorked world revolutions, the first by establishing he foundation of medical practice to be the study of hysiology, and the second by revealing, with the ssistance of an infinitely larger range of material quipment and recorded knowledge, the principles of sepsis that dictate the whole of medical procedure o-day, alike for the prevention, alleviation, and ure of disease In a fascinating address the President was able to show the existence of a arallelism between the two men which is remarkable, ven though it may be largely due to the acute and everential appreciation of Lister for the magnificent onceptions and fundamental performances of his ore-runner

The Hunterian Orator, in estimating the measure of the debt of the world to Lister and Hunter, compared the ideals of medicine, as established in the minds of the leaders of to-day, to those of enlightened soldiers for the cessation of war He enumerated the triumphs of operative surgery made possible by Lister, and longed for and sometimes foreshadowed by Hunter, thus introducing the apparent paradox that the direct developments of Hunter's researches and of Lister's fruitful leadership have been a vast multiplication in the range of operative surgery, which may appear to be rather an increase of war But those who are able to take a large view of the situation can see that the real objective is the ending of war For what is the war, as conducted by medicine, directed against? Against the pain, the disease, and the death of the human race Thousands of operations are performed to-day which could never have been attempted save for the wide wisdom and the intensive powers of research possessed by the two great leaders, but while those operations existed only in the imagination of Hunter and his school the victims descended to death through the valley of pain and disease—quickly or slowly they descended, without hope of escape and little hope of respite The war that is being conducted by modern medicine even though, in the operating theatre, it bears the closest resemblances to military performances, is a war that aims at and frequently succeeds in bringing peace Further, it is an extraordinarily hopeful form of war in that the old methods are ever ready to change and to submit to new discipline, as the range of knowledge is increased and collated when gathered from such resourceful allies as chemistry, physics, and physiology, with its biological implications The living progress of medicine is the glory of Hunter and Lister They are not to be praised as the inventors of any particular manœuvre or the discoverers of any valuable technique, but as the men who opened up to medicine a vista of victories, while providing opportunity for the wisdom of the world to play a part in its own salvation In the address delivered by Prof J M T Finney before the Hunterian Society we have eloquent testimony to the way in which Hunter's teaching permeated the culture of early America, the doctrines of Lister exercised a similar force throughout the world

The debt of humanity is equally divided between Hunter the great philosopher and Lister the great performer, a differentiation which is not meant to suggest that the leader in the eighteenth century was other than a remarkable technician, or that the leader in the nineteenth century was not a profoundly deep thinker As a matter of fact, which is well brought out in the latest Hunterian Oration, the methods of approach to the great problems of disease, as they unrolled themselves before the two men, appear wonderfully similar, and Sir Berkeley Moynihan indicates a suggestive similarity in their lives Each underwent a long and arduous apprenticeship—Hunter in the private medical school of his elder brother, and Lister in the wards and lecture rooms of Edinburgh and Glasgow Each, with much that was identical in their labours, strove to found boundless theories on a basis of exact knowledge, firmly laid and truly tested In the case of Hunter the immediate aim was mainly to acquire a knowledge of structure in relation to biological processes, while in the case of Lister comprehension of the processes of inflammation in relation to the manifestations of disease formed the first main objective of study And when the large results of their researches begin to appear each is in young middle age, but with a life time's record accounted for Hunter was 34 when he had placed to his credit by individual research the solution of biological problems whose existence had hardly been realised, and Lister was 33 years of age when he arrived in Glasgow, with results that can never be exaggerated, having behind him such a mass of researches made during the past seven years as, said the Hunterian Orator, would almost suggest that he was seeking to fit himself to be an experimental physiologist or pathologist rather than a surgeon The intensive nature of their early training led up to their magnificent achievements, while their devotion to the highest ideals of science secured for them the enthusiastic adherence of their followers

◆

TESTS OF HEPATIC FUNCTION

The enormous importance of the liver in the internal economy of the body has led to perpetual research during centuries, and the strange but definite fact that there is no clear-cut clinical syndrome which can be directly attributed to its dysfunction, as uræmia or steatorrhœa and glycosuria can be attributed to renal or pancreatic deficiencies, has in no way diminished our interest in this organ For however elusive the signs and symptoms of hepatic deficiency may be, it has long been clearly recognised that gross destruction of liver tissue by progressive disease, or a generalised poisoning of the hepatic cells make the prognosis very grave, especially in cases where operative treatment or the administration of such toxic drugs as chloroform or novarsenobenzol is contemplated

Practical Physics

By T G Bedford M A , F Inst P , Demonstrator of Experimental Physics in the Cavendish Laboratory, Cambridge, and Secretary of the Oxford and Cambridge Schools Examination Board London Longmans, Green and Co , Ltd 1926 Pp 425 10*s* 6*d*

The scope of the intermediate teaching in Practical Physics at Cambridge can be inferred from this book A good selection of experiments has been made, and they are described in a way which should make it possible for the student to go through his practical course with a minimum of personal attention from his teacher, though the author rightly holds that for the proper teaching of physics the supervision of a keen demonstrator is essential The ground covered is wide , in fact, were the student to go no further in the practical side of the subject he would still have a very fair all-round acquaintance with fundamentals, with the exception of subjects such as spectroscopy and radioactivity Within the range of the subjects covered we have nothing but praise for the adequate way in which the different sections are treated and the difficulties explained

Hygieia or Disease and Evolution

By Burton Peter Thom, M D New York E P Dutton and Co 1926 Pp 107 2*s* 6*d*

The influence of disease and especially parasitic disease, on evolution is a topic well worth serious discussion in the light of modern knowledge Dr Thom's treatment is hardly worthy of the subject It is vague, diffuse and scarcely correct in detail We find, for instance, on one page (p 80) the statements that the "dread shadow [of puerperal sepsis] that once threatened every pregnant woman has passed for ever ", that tuberculosis "has undoubtedly destroyed more lives than all other infectious diseases together ", that "all those who succumb to 'tuberculosis' are inherently of a type that are deficient in resistance" On p 98 we read of 'antityphoid serum—to prevent typhoid fever" He visualises (p 90) the time when progressive resistance will culminate in an absolute immunity of man to infections, forgetting that evolution and adaptation can occur in parasites as well as in hosts, and generally a good deal quicker in the former than in the latter However, it is to the good that the author is a cheery optimist with a sound belief in man's capacity to get round any difficulties which he meets

Self-Care for the Diabetic

For the Use of Diabetic Patients By J J Conybeare, *M C* , M D , F R C P Lond , Assistant Physician to Guy's Hospital London Humphrey Milford, Oxford University Press 1926 Pp 70 3*s* 6*d*

It is only within recent years that it has been realised that if a patient suffering from diabetes mellitus is to do well he must know as much as possible about the disease and of the principles which govern the dietetic treatment The recent books on the subject have been for the most part too technical for the average patient, and even the simplest of them has frightened and depressed more than one patient by references to diabetic coma and to cataract These pitfalls have been avoided by Dr Conybeare, who has written an excellent little book The chapters on the disease and on the principles of the diet are written in a simple manner and should be easily understood by the patient It would be an advantage if, in future editions, a graph was included of a blood-sugar curve after insulin as this would help the patient to understand its action more readily Some of the details given are hardly suitable for poor patients Thus absolute alcohol instead of methylated spirit is recommended for sterilising the insulin syringe and needles in order to avoid rusting, while the cheap alternative either of employing rustless needles or the addition of lysol to the methy spirit used for sterilising steel needles are not tioned Undue emphasis is laid on one specia paration of diabetic foods in the text and the such foods in the appendix might be extend include the diabetic foods which contain a goo of carbohydrate

The book should serve a useful purpose and relieve the medical attendant of some elem questions , on the other hand, if the pati intelligent it may also provoke further qu perhaps more difficult to answer

JOURNALS

Proceedings of the Optical Convention, 1 The Third Optical Convention met in Lon April, 1926 The previous conventions were 1905 and 1912, and the second and third m were thus separated by the war period in wh British optical industry made great advance. Proceedings form a valuable record of improv in theory and technique The papers deal wit side of optical science and several are, of cour cerned with the eye its mechanism and its A paper on some visual factors affecting the optical instruments deals with such matters acuity of vision and its relationship to the s of the eye threshold values and the effect of tion on vision and the optimum size of field in observational instruments —Two papers Aves and W Swann treat of the refractive d the eye from the statistical point of view papers the necessity of a greater uniformit conditions under which the tests are mad the method of recording data is emphasis Mechanism of Accommodation is the title o by E F Fincham, in which the anatomy of concerned is treated in detail and measur curvatures made by the author are recorde vidual differences were marked —A short Margaret Dobson deals with Heterophoria charting of this defect by Esdaile's myoph The problem of the anisometrope is dis some length from the optician's point of W B Barker —Conrad Beck contributes esting paper on Recent Advances in the Ma and Use of the Microscope The procee published at £3 and consist of two volumes c about 1000 pages They may be had Secretary of the Optical Convention 1 gardens, Exhibition-road London S W 7

Reports and Analytical Re

COW AND GATE MILK FOOD

ENGLISH FULL CREAM FOR INFANTS AND IN

(West Surrey Central Dairy Co , Ltd Gu Surrey)

This substance is stated on the label to be full cream milk, and to contain the equivale pints of milk " The contents of the tin 153 g (5 4 oz) and on analysis showed the composition :—

Moisture	2 81	per
Ash	6 16	,
Fat	25 75	,
Protein	26 43	,,
Lactose hydrate	38 02	,,
	99 20	,

This milk, which is of the "drum-dried is a good specimen of pure unadulterated milk, containing no added cane sugar, mil preservatives The fat is well up to the the moisture somewhat lower The clai tin contains the equivalent of two pints fully substantiated by the analysis It with warm water, and is quite free fro or greasy flavour behalf of the colliery company, has been 11 days in the witness-box, and his evidence, it seems, is even now not yet concluded In these circumstances it is not surprising that the judge does not desire to hear several additional experts whose evidence will travel over the same ground, if he is to limit the witnesses for the plaintiffs, he must also limit those for the defendants

How far is it likely that the judge s ruling would be applied to litigation in which a medical practitioner is personally concerned as plaintiff or defendant? Here two points may be borne in mind In the first place a Chancery judge sits without a jury Partnership disputes between doctors, in which professional conduct might be an issue, might conceivably find their way into a Court of Chancery, but the normal case in which negligence or malpraxis is alleged will usually be tried before a jury When there is a jury, it is for the jury—not the judge—to decide the facts If so, the jury—not the judge—is entitled to say when sufficient evidence has been heard upon a particular point The attitude of a juryman is sometimes unfathomable He may discount the evidence of all the experts impartially, or he may reckon its weight by the relative numbers of the experts rather than by their relative qualifications, he may even think, if the case is tried in the country, that his own local doctor is a better man to follow than some stranger from London But he is not to be told that he must only hear two experts and not three, or three and not four In the second place, it must be remembered that one or two experts cannot always cover the whole of the ground or deal with every technical aspect. The Swansea Corporation, protesting against the ruling under discussion urged that it might wish to call the evidence of experts in the separate subjects of mining, water supply, and geology The judge answered that he would not limit the number of witnesses if satisfied that "by reason of special circumstances' justice could not be done without hearing other experts; and, in any case, additional witnesses could be called even though experts, to speak to matters which they had personally seen The argument of the Swansea Corporation would often apply where a case turns upon medical evidence Recently, for instance, where a doctor was charged with performing an illegal operation, it was indispensable for the defence to adduce the evidence of expert pathologists, gynæcologists and anæsthetists It would have been intolerable if the defendant had been restricted to a maximum of two experts

There are practical limitations upon the number of witnesses already Learned counsel, who advise preliminarily what evidence is desirable and who are responsible subsequently for the calling of the evidence, know better than to weary with vain repetitions a tribunal which has already appreciated a point of fact or opinion The expert upon whose authority the litigant most confidently relies is generally the first to be placed in the witness-box, when his evidence is ended a sequence of lesser experts will add but little The taxing-master, too, contributes to the limitation of numbers, since it is known that he may disallow the costs of superfluous evidence But there are times when the risk of repetition must be run and when costs must be incurred without regard to their recovery The defence of his professional reputation is a cause in which a practitioner must employ every resource We cannot believe that judges will ever obstruct his right to call into the witness box every witness who may be deemed necessary for that purpose

Annotations.

"Ne quid nimis"

TREATMENT OF STOKES-ADAMS ATTACKS

FEW clinical incidents are so dramatic as a Stokes-Adams seizure. The suddenness of the onset the urgency of the symptoms, and the possibility of a fatal termination together create on the observer an impression never likely to be forgotten The unexpectedness of the calamity is not infrequently intensified by the fact that before the first seizure the patient has had little cause to suspect the existence of any serious derangement of his circulatory mechanism, and may in fact have led an active life Even physical examination between attacks sometimes reveals but little evidence of morbid changes in the heart. for though in most cases some grade of heart-block is present, instances do occur when even this is lacking. The mental anguish of these patients is often pitiful, and when their seizures follow one another in rapid succession they live in constant dread of impending death, hardly daring to move a muscle for fear of precipitating the next, and possibly the last attack. As in all paroxysmal conditions treatment resolves itself into abortive and preventive measures The latter are the more important, for in the great majority of cases individual attacks are of short duration Ventricular asystole implies not only that the normal impulses from the auricle are failing to reach the ventricle but also that the lower centres in the heart have not set up an independent rhythm. It is not surprising therefore that Stokes-Adams seizures should most frequently occur during the unstable phase when partial heart-block is tending to become complete or when complete block is reverting to normal rhythm The increased incidence of attacks during such transition periods is well illustrated by a case recorded by Parkinson and Bain in our columns [1] in 1924 Failure of the auricular impulse to reach the ventricles may sometimes be due in part at least to an increase in vagal tone Under these circumstances atropine may relieve the condition, but in the treatment of the Stokes-Adams syndrome the therapeutic effect of this drug is as a rule disappointing When, on the other hand, the block is due not to vagal influence but to some structural lesion of the bundle or to damage caused by some toxic agent the rational line of treatment is to endeavour to increase the excitability of the muscle of the ventricle itself. This may sometimes be achieved by subcutaneous injections of adrenalin (5 to 10 minims of the 1 in 1000 solution) Complete heart-block is sometimes abolished by adrenalin whilst in other cases although the block remains unaltered ventricular standstill is prevented S A. Levine [2] has recently reported a remarkable case in which on two occasions Stokes-Adams attacks lasted for several minutes and ventricular activity was re-established by injecting adrenalin directly into the heart. The most recent therapeutic agent employed in this condition is barium chloride, a drug known to increase the excitability of the ventricle under experimental conditions in animals, and A E Cohn and Levine have shown that clinically it sometimes appears to prevent recurrence of the syncopal attacks and recommend a dose of 30 mg. four times a day by mouth. Unfortunately neither adrenalin nor barium appears to be efficacious in all cases, though in the present state of our knowledge they offer the best prospect of preventing the attacks.

INTELLIGENCE OF THE NEGRO

THE problem of the negro is a hardy perennial in the United States and it was inevitable in a country where so much work has been done with intelligence tests that their aid should be invoked in order to determine whether his assumed racial inferiority is

[1] THE LANCET, 1924, ii 311

[2] Boston Med and Surg Jour, 1926, cxcv., 1147

Interest in the liver has been further stimulated by the more exact classification of cases of jaundice which are now very generally recognised as falling into three classes (1) those in which there is gross mechanical obstruction to the biliary channels, (2) those in which the liver cells themselves are so disordered that the proper excretion of bilirubin from the blood cannot be accomplished, and (3) those in which the jaundice is the consequence of excessive hæmolysis, the blood being saturated with bilirubin of extra-hepatic origin Intent on the elucidation of such problems, laboratory workers have long sought for chemical tests which may demonstrate pathological changes in the liver cells, and hence any defect in the general physiological capacity of the liver Such tests have been suggested in great numbers, and it must be recorded that they have usually had but a transitory popularity Almost as fast as they are devised they fall into disuse, and it should be placed to the high credit of medical research that improved and novel tests are investigated perpetually by energetic workers who refuse to allow disappointment to convert them to pessimism

In our present issue we print the results of investigations into two liver tests which, if not entirely novel, have not perhaps received the attention in this country which they appear to deserve Essentially there is no great difference between the two, for in each a simple sugar is administered by mouth and the test consists in ascertaining the change, if any, which occurs in the concentration of sugar in the blood at subsequent half-hourly intervals In the test described by Dr D T DAVIES galactose is employed This is given in a dose of 40 g dissolved in 400 c cm of water, samples of venous blood being collected at half-hourly intervals for several hours afterwards In addition to these blood samples, the urine is also collected, though the conclusion of BAUER, one of the German observers, that galactosuria was the one positive sign of abnormal liver function is not fully borne out by the latest investigations The blood-sugar curve has, in Dr DAVIES's hands, proved more useful, no great rise in this curve being observed save in those cases where the hepatic cells had been grossly damaged Thus normal persons, patients with gross obstructive jaundice, and subjects with pernicious anæmia and acholuric jaundice, alike showed little or no rise in the blood-sugar after the ingestion of galactose, whilst those with catarrhal or toxic jaundice, cases of malignant disease with secondary deposits in the liver, and cases of cirrhosis following syphilis or chronic alcoholism gave very definite increases in the blood-sugar after galactose owing to the serious derangement of the glycogenic function of the liver Mr GORDON KING has employed lævulose, of which sugar he gives 45 g in 100 c cm of water to the fasting patient Subsequent blood analyses again were used to determine the curve of blood-sugar In 53 cases investigated it was found that only those subjects in whom gross damage to the liver cells was present showed a marked and continued rise in the concentration of sugar in the blood It is clearly too soon to discuss the ultimate value of these tests, though any attempt to give a firmer outline to the vague country of "liver disorders" is to be commended The transitory nature of our confidence in the virtue of certain other tests has already been alluded to, and is exemplified in the interesting article by Dr ERNEST BULMER who, in the current number of the *Quarterly Journal of Medicine*, records the unsatisfactory results which he has obtained during his investigation of the bromsulphalein test In this test, devised by ROSENTHAL, a dye, bromsulphalein, is injected into a vein, and the amount of such dye remaining in the blood serum half an hour later is estimated by a relatively simple colorimetric test Earlier investigations appeared to promise that only in cases of defective liver function would there be marked retention of the dye, and indeed that the degree of retention would give an accurate indication of the extent of hepatic deficiency From Dr BULMER's results it would appear that such hopes were groundless, and that there is too gross a margin of error to leave much practical utility in the test Somewhat similar disappointment has been experienced in the case of the test associated with the name of Prof H van den BERGH The hope that this test would supply a ready method of differentiating the various types of jaundice has not been fulfilled, though, as Dr DAVIES points out in his article to day, it has proved of value in estimating the degree of bilirubinæmia

The critical clinician, when reading through the protocols of inquiries such as those to which we here allude, is apt to point out how little they add to the information which is already obtainable by careful clinical examination The degree of jaundice can be as delicately estimated by the human eyes as by almost any laboratory test, the size of the liver and its consistency give information as precious as any that the biochemist can bring forward, and it is indeed to the clinician that the laboratory worker turns when seeking the interpretation of the subtleties before him But to recognise these facts is not to disparage the chemists' efforts, for most important results have already been obtained of which the more precise classification of jaundice is an example, and if the laboratory now settles the diagnosis in but one case in a hundred, that one is to the good and is the probable forerunner of further diagnostic success

◆

THE LIMITATION OF EXPERT EVIDENCE

IN the course of a case which has occupied his judicial attention for several weeks, Mr Justice TOMLIN has ruled that he will not hear more than two expert witnesses on either side The decision, discussed by a legal correspondent upon another page, has interest for the medical profession which furnishes so great a proportion of the expert evidence given in courts of law It may cause some apprehension too The medical practitioner may find himself involved from time to time in litigation in which professional negligence or malpraxis is alleged, will he not be prejudiced if the court curtails his right to summon all the expert witnesses he may consider necessary? Even in a civil action, still more in criminal proceedings, any such curtailment might amount to a denial of justice We can only assume that no general interference of this nature is intended, indeed the circumstances in which the learned judge delivered his ruling appear to have been exceptional A colliery company had asked the Court of Chancery to restrain the Swansea Corporation from filling a certain reservoir with water on the ground that, if the corporation carried out its purpose, the mine workings would be flooded The case had occupied 26 days when Mr Justice TOMLIN made his pronouncement, it has since lasted a further fortnight, as no doubt he foresaw, and it is not yet ended He has adjourned the action for a month in the hope of making progress with the other cases in his list which were promising to be indefinitely postponed Already expenses have been heavy, the existing costs are estimated at £40,000 One expert witness, called on and not a complete one. It must be remembered also that Walker, Teale, and Embleton worked with animals with an intact bladder and urethra, and that their contention that the mechanism of spread was by the lymphatics only applied to cases of ascending infection unassociated with obstruction. When obstruction is present in the lower urinary passages it is more likely that the infecting organisms ascend along the column of stagnant urine lying in the ureter.

SANITATION OF THE PORT OF LONDON

Dr. W. M. Willoughby, in his report for 1925 to the Port of London Sanitary Authority recently published, mentions that no case of plague, cholera, or typhus fever had to be dealt with, and that no plague-infected rat was found in the port. All vessels from abroad are visited by a medical officer; ships from "infected" or suspected ports are boarded and examined on arrival, and later, in dock, come under further scrutiny by a sanitary inspector. Ten deaths were notified, seven from pulmonary tuberculosis, and one each from small-pox, enteric fever, and measles. Three ships reported they had had a case of suspected plague on board during their voyage, but it is doubtful if any of these was really plague. Twenty-one ships reported outbreaks of small-pox since leaving their port of origin, and four cases were landed in London. In eight cases complaint seems to have been made in the stage of initial fever, but its significance was rarely, if ever, recognised. As soon as the disease appeared the crews were vaccinated, but much time would have been saved had the crews been kept continuously protected, so that these infections could not have occurred. A seaman from a ship was found at Stepney to have small-pox; his ship was examined and one of the crew, well vaccinated in infancy, was discovered to be recovering from a characteristic, though very slight, attack of small-pox. That case dated back three or four weeks, and the patient's brother and two others of the crew had been left behind at the last port suffering with "influenza"; on inquiry being made they were found to be in a small-pox hospital. The one slight missed case seems thus to have caused at least four others.

In the Port of London, when cases of infectious disease have occurred, cabins or compartments are now disinfected by sulphur fumigation followed by washing down with disinfectant, infected articles and textiles being disinfected by steam. To get rid of rats 40 ships were fumigated with sulphur (average of dead rats found, 62), and 12 with hydrocyanic acid (average of dead rats, 54). A paper reproduced in the report tells how thoroughly rat-proofing is being done at the New York Quarantine Station. The work there is based on the three following principles: (1) Rats want food and water, so these must be kept out of their reach; (2) they want shelter and nests, so there must be no harbourage for them and no rubbish left about to help in nesting; (3) they must be kept in the open by blocking up their runways. Skilfully used, these measures get rid of rats and are inexpensive; Dr. Willoughby thinks that if they are thoroughly carried out they will stop rat-borne plague and the need for frequent disinfestation. A total of 27,128 rats were caught and destroyed in the year—12,746 in the warehouses and 14,382 on ships in docks and river. Of those caught in warehouses ashore, 1929 (1338 black, 591 brown) were examined for plague, but all were free. The visits of medical inspection paid to ships totalled 15,156, and 200 ships were found defective. The principal complaint was of dirty quarters (1535), the most numerous after that being lighting (57), leaky decks (48), sanitary conveniences (45), and ventilation (44). But it was not only ships that were defective; nuisances were also found on shore premises, of which 924 were dirty, and 65 had unsatisfactory sanitary conveniences.

The inspection of imported food is a very important branch of the work of a port sanitary authority, especially of that of the Port of London, and in the year under review over 1400 tons of unsound food had to be condemned, including 109 tons of meat. Some 56,000 beef tongues were examined, and about 2 per cent. of these were found to be infected with actinomycosis. The quantities mentioned are sometimes considerable; the eye is caught by amounts such as 196 tons of dates and 534 tons of "sugar sweepings." The latter may not have contained much sugar, for it is mentioned that chocolate sweepings in another port were found to contain metals, woodwork, glass, and flinty materials. The transport and handling of meat is being carried out in a cleanly manner under the Public Health Regulations, 1924. Under the Public Health (Imported Food) Regulations, 1925, rendered fats are only allowed to be imported if certificated; if not certificated they are stopped unless a guarantee is given that they will be exported or used in some manufacturing process not connected with food. A 10-ton consignment of orange pulp in tins was seized, because the contents had fermented, had been resterilised—thus losing food value—and resealed, the result being that the juice now contained too much tin. Dried fruits are treated with sulphur in the port to kill larvæ and this prevents deterioration. No reference is made to the question of latrines about the docks, which last year's report said was having attention.

PHYSIOLOGICAL CURE FOR MUSCULAR CRAMP

Dr. G. W. Fitz[1] has recently described a simple form of treatment which he has used in two cases of muscular cramp. One of the patients was an active, strong man of 190 lb. weight. In early life he had had occasional cramp in the feet, and at about the age of 53 had sustained a moderate sacro-iliac strain; dental abscesses had also been present for an unknown length of time. The cramp seizures began when he was 55 years old. They usually came on at night during sleep, and involved the quadriceps and inner hamstring muscles of the lower limbs. He noticed that they were worse after fatigue from standing, and during the attack the agonising pain indicated that every nerve in the hard mass of muscle was pinched as in a vice. After 10 or 20 minutes the muscle became soft, and though a new contraction often started it was of shorter duration and stopped more rapidly under the influence of radiant heat from a fire. Relief from attacks was only obtained by the use of salicylate in full doses, and administration of this drug was continued over a period of two years. The patient's teeth were then extracted; some slight joint trouble was arrested, and with improved health the cramp stopped for two years, after which, however, it began again. On the theory that cramp is due to alkalosis, it occurred to Dr. Fitz that the seizures might be arrested by causing retention of carbon dioxide, and for this purpose he uses the following method. At the first indication of cramp the breath is held, and an empty rubber bag of 3 pints capacity is applied to the mouth; air is then expired into it as late and as slowly as possible. Inspiratory breaths are taken from the bag, but as this is not very large a little of the outside air is sucked into it at each inspiration to meet the deeper breathing which the deficient oxygenation causes. Dr. Fitz states that this procedure prevents oxygen-want, but does not hinder CO_2 accumulation; but the statement is certainly open to criticism since dilution of expired air with atmospheric air will obviously diminish the percentage of CO_2 as it increases the percentage of oxygen. The result of rebreathing from the bag is said to be that the cramp is at once aborted with only a few weak twinges to indicate how severe the attack might have been. Dr. Fitz considers that the condition in the patient he describes is analogous to the tetany or cramp-like effect produced by over-breathing, and he suggests that in his own case the cramp may arise from respiratory acceleration in sleep as the result, for instance, of excitement in dreams. As he points out, there are various conditions of tetany which suggest real, and, if so, of what degree The most recent of such inquiries to come to our notice is a survey of the children in the negro public schools of Atlanta Miss Virginia T Graham, psychologist to the U S Health Service, describes the methods and results, and was presumably responsible for the work Over 3000 children in five schools were the subject of experiment They were first of all tested by the Otis group intelligence scale, and those who made low or doubtful scores were then given individual tests, for this purpose the Stanford-Binet scale was principally relied upon, but was supplemented by three practical tests, the well-known Healy construction A, and two others less known here, the Kohs block design test and the Lincoln hollow square The results of the group tests were compared with Otis's own norms for white children of 200 cities All such comparisons are, of course, subject to the criticism that the two races have not an identical social and educational environment Making all allowances, however, the results show that on the tests given the negro children, at all ages above the lowest, made averages lower than those of white children, and that the discrepancy at each age rises with the age, they also show that greater variability of performance is found among the whites than the negro, the negro group tending to hang more closely round the average, thus giving smaller possibility of superior capacity in individuals Judged qualitatively on the basis of the tests, the negroes exhibited a lack of sensory discrimination and an inability to criticise their own work and recognise failure in it In practical and rote work they showed more efficiency These results are in accord with those of previous investigators in this line of work, but with regard to the degree of discrepancy of the races there is still much disagreement The writer of the report makes no greater claim for the value of the results obtained than they will bear; she claims no infallibility for the tests, and she allows for the "distorting influence" of "attitudes and interests" It may be, however, that so far as the social and economic adequacy of the negro relative to the white is concerned, temperamental differences between the races are of more importance than the differences of intelligence which the tests are supposed to reveal Until tests are measures of the complete man and not merely of an undefined "intelligence" inferences and predictions of individual or racial adequacy must be made with caution

PATHS OF RENAL INFECTION.

THE mechanism of ascending infections of the kidneys has long been a subject of dispute There are three paths along which organisms from an infected bladder may pass to the kidney—by the blood stream, by the lymphatics surrounding the ureter, and by the urine Much experimental work has been done to decide which of these paths is the one taken by organisms in ascending infections of the kidney In the December number of the *British Journal of Experimental Pathology* are published the results of the experiments carried out by C H Kellaway, C J. L Brown, and F Eleanor Williams Their method of investigation was to introduce various organisms into the bladders of guinea-pigs after producing a partial obstruction of the urethra and tying the right ureter It was found that the usual result of this inoculation of the bladder was to produce an infection of the pelvis of the left kidney Similar results have, of course, been obtained in the past by other experimenters, and taken alone these experiments do not furnish information as to the path taken by the infecting organisms But whereas previous experimenters have regarded sterile blood cultures made at the autopsy as a proof that the infection could not have occurred via the blood stream, Kellaway, Brown and Williams show that such an assumption is unjustifiable In certain of their animals organisms could be grown from the blood during life although the blood cultures made at the autopsy proved negative, proving that blood cultures in the dead animal could not be relied upon to detect bacteriæmia during life

In another series of animals experiments made by Kenneth Walker, F H Teale, and Dennis Embleton on the ascent of organisms via the chain of lymphatics surrounding the ureter was repeated The above named investigators had found that, if a loopful of *Bacillus prodigiosus* was placed in the urethra of a guinea-pig, and the animal was killed 6 to 12 hours later, the same organisms could be recovered from the capsule of the kidneys, although the blood and the urine of the animal were sterile Kellaway, Brown, and Williams failed to obtain similar results except in one single instance They are not, therefore, inclined to support the view that infection via the lymphatic chain surrounding the ureter is of common occurrence But although their experiments showed that the possibility of the renal infection being blood-borne could not be put out of court by the fact that blood cultures made at the autopsy were sterile, they are not inclined to think that organisms travelled in the blood stream A blood-borne infection would not explain the fact that in the majority of their animals it was the left untied kidney that became infected, the right kidney, whose ureter had been ligatured, remaining free The mere tying of the ureter had apparently no effect in determining the side on which a blood-borne infection developed In four out of five experiments in which organisms were injected into the blood stream 24 hours after ligature of the right ureter the kidney on the tied side became infected If, however, two, three, or four days were allowed to elapse between the tying of the ureter and the injection into the blood stream of organisms no infection of the hydronephrotic kidney occurred

In the hope of obtaining more information as to the path taken by infecting organisms, another series of experiments were made with suspension of insoluble particles introduced into the bladder In five experiments in which the urethra was partially obstructed and a suspension of carmine introduced into the bladder, particles of carmine were invariably present in the pelvis of one or both kidneys after from two to three and a half hours When the sacral nerve roots were destroyed, so as to produce paresis of the bladder, the ascent of pigment was not so regular, but occurred in four out of eight animals killed two to four hours after injection In these experiments particles were invariably found within the lumen of the ureter and pelvis and never in the wall of the ureter or in the accompanying lymphatics These experiments, together with others carried out on cats and rabbits, prove that when the urethra is partially obstructed or the nervous mechanism of micturition disorganised by division of the sacral nerve roots, the introduction of pathogenic organisms of pigment granules into the bladder is followed within two to three hours by their ascent into the pelvis of the kidney In the opinion of the authors this ascent occurred too rapidly to be accounted for by a blood infection although, as previously stated, the fact that the blood cultures at the time of the autopsy were sterile could not be taken as definite proof that a bacteriæmia had not been present during life

Since they had failed to confirm the findings of Walker, Teale, and Embleton on the subject of an ascending spread via the lymphatics, they were led to the conclusion that the organisms and particles ascended along the lumen of the ureter These results are similar to those obtained in 1890 by J C F Guyon and J Albarran when working with dogs and rabbits in whom a complete retention had been produced They are also supported by the work of G E Brewer in 1911, who produced pyonephrosis by injecting organisms into the bladders of dogs with artificial retention The experiments of Kellaway and his colleagues, however differ from those mentioned above in that the bladder injections were made in the presence of a partial urethral obstruction

[1] Public Health Reports of the United States Public Health Service, vol xli, No 49, Dec 3rd, 1926

At the Mothers Hospital in Clapton the post-partum morbidity appeared to be less in the venereal block than in the clean blocks This hospital was associated with hostels and pregnant patients known to have been infected were thus admitted some months before their confinement was due In a large proportion of these cases the gonococcus could not be found the usual secondary infection having supervened. Dr. Logan attributed the succession of normal puerperiums in these cases to early and thorough treatment. and Dr D Nabarro also commented on the extraordinary way in which copious vaginal discharges cleared up under hospital conditions The discussion raises the interesting question as to how far the systematic antenatal disinfection of the vaginal flora if it were practicable might reduce puerperal morbidity. Those patients who have been segregated in a modern V D hostel for weeks or months prior to admission have not only had their vaginal tracts continually disinfected. but also have had no chance of becoming infected by other organisms during coitus late in pregnancy. Many uneducated women still believe the old superstition that regular intercourse near term is beneficial, and will help them to have the much-desired easy confinement Another point which favours the hygienic condition of the inmates of a hostel is that they are accustomed to take several baths a week, an almost impossible practice for the poor-class married woman living in her own home. Hostel patients are also no doubt, given regular aperients and so another fertile source of pyrexia in the puerperium—*B coli* infection of bladder or kidney—is less likely to occur. Finally, these young women are under daily supervision and malpresentations of the child are more likely to be noticed and remedied before labour. thus avoiding the need for undue manipulation during labour.

SONNE BACILLUS DYSENTERY IN BRITAIN

FOLLOWING Dr. R Richard's account of an outbreak of bacillary dysentery in children at Aberdeen [1] where, though most of the cases were due to Flexner bacillus four cases were caused by the Sonne bacillus Dr. F H A. Clayton now (p 391 of this issue) reports a case of Sonne dysentery in England. having a possible contact relation to the Aberdeen epidemic In one of the Aberdeen Sonne cases the patient suffered from an arthritis accompanying the dysentery, such toxic arthritis not having been hitherto recorded in association with this organism. After the dysentery epidemics of 1668–72 in England, Sydenham (1672) described arthritis following a definite clinical attack of dysentery This was forgotten but the dysentery epidemics of the late war made this toxic arthritis in Flexner and Shiga dysentery well known Dr. S H Clifford [2] has brought forward evidence to show that one type of arthritis deformans in children may be due to a past or present infection with Flexner bacillus which has not produced a recognisable clinical syndrome of dysentery These facts suggest that all cases of arthritis, at any age, of doubtful ætiology should be examined for infection by dysentery bacillus Dr. Richards noted that in dysentery the insertion of a finger in the rectum caused tenesmus with expulsion of blood and mucus whereas in intussusception the rectum is large and roomy and no tenesmus is evoked This is a clinical observation of some importance, for in this country acute dysentery in the child may easily be, at first regarded as intussusception The subject of digital rectal examination not unnaturally suggests sigmoidoscopy—for subacute cases Tropical practitioners have now learnt from experience that sigmoidoscopy is indispensable for the accurate diagnosis of all cases of so-called colitis The method has made it much easier than formerly to demonstrate the causal organism, by culture or microscope, in the mucus picked off an ulcer or inflamed patch of mucosa. Its routine use has shown, as Dr. Richards surmised that bacillary dysentery is not so rare among some populations as was generally believed. Thus K Saisawa and B Tanabe [3] in the examination of recruits in the Japanese Army in Tokyo. found that sigmoidoscopy gave more successful results than even fresh cultures from stools and many apparently healthy carriers of dysentery bacillus were detected by its aid Furthermore the sigmoidoscope revealed that the great majority of these were not healthy but. in fact. were very mild cases of dysentery with slight lesions in the colon—so mild and so slight that infection with dysentery bacillus had not been suspected.

THE PRINCESS MARY, F R C S

ON Feb 14th Princess Mary. Viscountess Lascelles, was admitted an honorary Fellow of the Royal College of Surgeons of England. being the first woman to receive this distinction. Wearing the robes of a Fellow she attended the Hunterian Oration delivered at the College by Sir Berkeley Moynihan. the President and published at the beginning of this issue of THE LANCET. In the evening the Hunterian Festival Dinner was held at the College After the toast of the Memory of John Hunter had been honoured in silence. Sir Cuthbert Wallace vice-president of the College proposed that of the Guests. To this Lord Riddell replied and passed appositely from some jocular words instigated by the menu. as to the ability of medical men to eat whatever they felt inclined. to a wise warning as to the depressing influence of the broadcasts in the press as to the harmfulness of many common forms of diet The toast of the President and Hunterian Orator was proposed by Viscount Lascelles who acknowledged the high appreciation of the Princess Mary of the honour conferred upon her by election to the Fellowship of the College He delivered a message to the President from the Princess signifying that her Royal Highness considered the diploma as setting a seal on work which she had attempted during the last six or seven years as the war had brought from her personal work in the alleviation of suffering.

THE Home Secretary has appointed Dr G. Roche Lynch to be Senior Official Analyst to the Home Office in succession to the late Mr John Webster. Dr. Lynch has since 1920 held the appointment of Junior Official Analyst to the Home Office.

WE offer congratulations to Dr. John Moore Swain of Long Clawson Melton Mowbray. who has recently celebrated his hundredth birthday Dr Swain became a licentiate of the Society of Apothecaries in 1849. and a Member of the Royal College of Surgeons in 1850

THE next social evening of the Royal Society of Medicine will be held on Monday. Feb 21st at 8 30 P.M Fellows and guests will be received in the Library by the President and Lady Berry. and at 9 30 P M Mr. Percy Flemming will give an illustrated address entitled Topographical and Medical Notes on Harley-street There will be an exhibition of prints and maps of the neighbourhood.

THE forthcoming revision of the International List of the Causes of Death discussed in our leading article last week will be undertaken by a conference called, as in former years by the French Government. So far there has not been universal agreement that the Health Section of the League of Nations should undertake the task of arranging conferences to deal with this question The League is however. attempting to collate recommendations from this and other countries alkalosis as their cause Amongst them is the loss of hydrochloric acid from the stomach in vomiting from pyloric stenosis or in gastric fistula, but in other conditions more detailed investigations have thrown some doubt on the close application of the theory J A Campbell[2] has recently suggested that all forms of tetany are primarily due to oxygen-want, and alkalosis—whether due to overdosing with alkalis or to any other cause—will act by hindering the blood from delivering up its load of oxygen, as Barcroft and his colleagues originally pointed out Taking these suggestions together with Dr Fitz's observations, it would seem that an even better way of treating cramp might be the simultaneous administration of oxygen and carbon dioxide, though this would not be nearly so simple as the method he has devised

TONSILLECTOMY AND ACUTE RHEUMATISM.

THERE is close agreement between all observers as to the high frequency of tonsillar disease in rheumatic children, percentages round about 80 being usually quoted On the other hand, there is wide disagreement as to the value of tonsillectomy in preventing rheumatic manifestations In the report[3] of the special subcommittee on rheumatic heart disease in children appointed by the British Medical Association Dr Reginald Miller pointed out some of the fallacies in the various methods previously employed in investigating this problem, giving the results of his own experience in the study of rheumatism as it occurred in children whose tonsils had been removed He showed that whereas arthritis had been present in 38 per cent of his cases before tonsillectomy recurrence of acute joint inflammation occurred in only one of those showing acute rheumatism after operation Closely similar results are reported in a recent paper by Dr O Holsti on the course of acute rheumatic arthritis after treatment of inflammatory processes in the upper air-passages[4] These results are based on a study of 35 cases of acute and relapsing rheumatic arthritis seen at the Medical Clinic of the University of Helsingfors There were 13 males and 22 females, and their ages varied from 10 to 60 years Typical polyarticular acute attacks occurred in 11 cases for the first time just prior to their admission to hospital, while in the remaining cases there had been two or more earlier typical attacks On admission to hospital each patient received salicylates in large doses with local applications to the joints, and the acute stages usually passed quickly Treatment of infections of the nasopharynx and mouth was generally not begun until the acute attack had completely subsided, but exceptions were made in certain cases with protracted convalescence and very marked inflammatory processes in the upper air-passages No harmful effect was seen in any case, even when the treatment was begun early (Dr Miller made the same observation with regard to the harmless nature of tonsillectomy in his cases) The measures taken consisted of tonsillectomy, operations on infected nasal sinuses and careful attention by a dentist to all inflammatory processes in the mouth The cases were then observed over a period of four and a half years and in no case did a true relapse occur in a purely rheumatic patient who had reached the age of puberty One man of 45 with heart disease died after gangrene of the leg occurred, necessitating amputation, and one boy of 10 succumbed to pneumonia and acute carditis eight months after tonsillectomy In two other cases relapses occurred, but one was complicated by the presence of gonorrhœa and the other was a case of hæmophilia Some of the remaining patients had minor manifestations of rheumatism from time to time, which Dr Holsti regards as abortive attacks, but over 50 per cent remained completely healthy This series of cases is undoubtedly small and the type of disease must have varied considerably with such a wide disproportion in the ages—namely, 10 to 60. Nevertheless the treatment of inflammatory processes in the upper air-passages does appear to have been beneficial in preventing the recurrence of the rheumatic infection in the joints On the other hand, Dr Miller had shown in his paper that the occurrence, or recurrence, of chorea is not controlled by tonsillectomy Such opposite results suggest that the disagreement upon the value of tonsillectomy and other measures in preventing rheumatic manifestations is not likely to disappear unless each manifestation is dealt with separately, since the total clinical picture resulting from rheumatic infection is too complex to permit of simple analysis

ENDEMIC TYPHUS IN SOUTH-EASTERN UNITED STATES

WE recently[1] drew attention to a report by Dr William Fletcher and Dr J E Lesslar on a disease in the Federated Malay States resembling typhus in clinical symptoms and Weil-Felix reaction, but differing from it in its low infectivity and the absence of any evidence of its being transmitted by lice A somewhat similar disease has since been described as prevalent in the South Eastern United States by Dr Kenneth F Maxey,[2] under the title of endemic typhus or Brill's disease The cases gave a positive Weil-Felix reaction and were clinically indistinguishable from typhus fever except in regard to their relative mildness and low fatality rate, which are characteristic of that form of endemic typhus known in the United States as Brill's disease Apart from a group of cases in the State of Alabama and in Savannah and Galveston, on which his report is based, Dr Maxey has collected evidence of the existence of mild typhus corresponding to the description of Brill's disease in other cities and towns in North and South Carolina, Georgia, and Florida The epidemiology of the disease seemed to differ considerably from that of typhus in the eastern hemisphere In the first place it reached its maximum in the summer and autumn, in contrast with the high winter and spring incidence of typhus in the Old World Secondly, as in the Federated Malay States, there was no evidence that infection was transmitted by the louse, which is the usual carrier of ordinary typhus It did not select the poor and uncleanly, but occurred among all classes, and no cases were found in prisons or asylums Dr Maxey suggests that the source of infection in this disease is elsewhere than in man, and is to be found in rodents, probably rats or mice from which it is occasionally transmitted to man This hypothesis is compatible with the following epidemiological characteristics (1) the uneven focal distribution of the disease, (2) its sporadic occurrence; (3) its apparent lack of communicability from an infected person, (4) its association with the place of business rather than with the home—particularly with those premises in which foodstuffs are handled or stored; (5) the recurrence of cases on the same premises after considerable intervals of time, and (6) its seasonal incidence.

THE PUERPERIUM AFTER GONORRHŒAL INFECTION

THE extra attention given in maternity hospitals to pregnant women known to have been infected by the gonococcus has evidently led to such good results that it is tempting to try to draw a moral of more universal application At the Cambridge meeting of the Medical Society for the Study of Venereal Diseases, reported in our last week's issue, Colonel L W Harrison expressed his conviction that the gonococcus was responsible for much puerperal septicæmia In his experience, however, the cases in the venereal wards of a maternity hospital ran a more level temperature than those in the other wards Dr D C Logan confirmed this impression

MATERNITY AND CHILD WELFARE

CONFERENCE AT NEWCASTLE-ON-TYNE

A CONFERENCE was held on Feb 10th, under the auspices of the Maternity and Child Welfare Group of the Society of Medical Officers of Health, Dame JANET CAMPBELL presiding. All parts of Great Britain sent representatives who were entertained by the Lord Mayor of Newcastle at a reception on Feb 9th and at luncheon on Feb. 10th. On Feb 11th maternity and child welfare centres in Newcastle and Durham County were visited, also various voluntary institutions having the care of children.

In reply to the civic welcome Dame Campbell said that this was the first conference of its kind held in the North of England. It was a purely medical conference. When they had had meetings in London they met not *only* medical colleagues but lay colleagues interested in maternity and child welfare. That had its advantages, but it tended rather to hamper discussion of medical topics, so that a meeting at which work could be discussed from the medical aspect only was welcome.

Dr A F G SPINKS opened the conference by reading a paper on the

Development and Future of Maternity and Child Welfare

He said that the development of the maternity and child welfare movement was probably the most convincing of the many signs of an awakening public interest in public health. It was almost unheard of 25 years ago, and yet though it had been started with all the financial and other disabilities inseparable from voluntary activities it had nevertheless gripped the imagination from the outset and had made for itself a safe and permanent abiding place in national affairs. To-day nearly every district—both urban and rural—had its maternity and child welfare scheme, and in England alone there were more than 2000 centres from most of which came reports of rapidly increasing attendances. At the Newcastle centres the attendances had increased from 4000 in 1918 to 50,000 in 1926. Dr Spinks traced the development of child welfare work from a centre established in Ghent in 1901. In 1924–25 the total expenditure on maternity and child welfare work in this country amounted to about 1½ million pounds, which represented less than one halfpenny a pound in a national budget of over 800 million pounds—not a large sum to spend on so important an object. Preventable ill-health cost the nation many times that amount annually. Those concerned with promoting maternity and child welfare had two main objects in view: first to maintain in good health those who were already healthy—practically every child was healthy at birth—and secondly to improve and increase national efficiency. Thus in principle the movement was essentially preventive and, since it dealt with the health of the public at the outset of life, it must be the basis of public health. Experience had proved that a great deal of the suffering prevalent among young children was due not so much to want of money as to want of knowledge, and unfortunately this want of knowledge prevailed on a vitally important subject from the child's point of view, that was its proper food. At the present time the bottle-feeding of infants was rampant, and unless the craze was checked England would become a bottle fed nation. There was nothing but teaching at *maternity* and child welfare centres to save us from such calamity.

The future of the work was assured because it was inconceivable that we should ever be allowed to slip back to the days when infants and young children were allowed to be the victims of undisturbed indifference or mismanagement, and needlessly sacrificed. Rather did he see maternity and child welfare expanded until it embraced within its benign fold every expectant mother and every child irrespective of class. He thought he saw the day coming when we should have health visitors with higher qualifications, and perhaps, some day, with medical degrees. The *health and welfare of our mothers and children* were national assets, and, as such, ought not to be left to the uncertain caprices of voluntary efforts which—praiseworthy though they were—must always be handicapped by want of money, and by their charitable nature, which made them offensive to a large section of the community.

Dr Spinks envisaged the day when infants' hospitals, few in number at present, would be numerous and when many of those in industrial areas would have their own country or seaside convalescent homes. The future would also bring a wide extension of open air and natural and artificial sunlight treatment, and unnecessary artificial feeding would be rigidly checked or abolished altogether. A halt must not be called in this work until every preventable calamity that befell women and children had been studied with good effect. When that day came there would only be one thing more for the maternity and child welfare movement to do, and that was to pass on the preventive principles upon which it was founded to the general public, so that instead of having as now an army of doctors curing disease we should have an army of doctors preventing it.

In the course of the discussion Dr MARION MACKENZIE (Leeds) expressed the opinion that maternity hospital nurses should be better trained. They did not know enough about the feeding of infants.

Dr CHRISTINE THOMSON (Durham) suggested that one of the greatest obstacles to the progress of child welfare work lay not in the difficulties of finance, nor in a lack of public interest, but in the scarcely veiled opposition of the general practitioner. The general practitioner regarded the tuberculosis officer or V D officer as a specialist, but did not apparently regard the medical welfare officer as a specialist even in infant feeding and frequently would alter the diet of a dyspeptic baby without consulting the welfare officer.

Dr ELIZABETH LANE (Newcastle) spoke of the enormous increase of artificial feeding since she first attended a welfare centre in 1913. One reason was that many mothers did not know how to breast-feed children successfully. The result was early evidence of indigestion and a consequent weaning of the baby simply through ignorance. A second reason, perhaps equally important, was the enormous amount of free food that had been distributed throughout Great Britain in recent years. This encouraged the worst type of mother—the young mother, married on the dole and irresponsible, living with her own or his people. A baby arrived and she was only too anxious to hand it over to its grandmother to be fed with free food, because then she was able to go out and enjoy herself. Weaning often occurred soon after a mother got up when there was a temporary failing of breast milk. Then was the time for the health visitor to give useful advice.

Dr MARGARET EMSLIE (London) expressed the opinion that one of the chief difficulties in connexion with breast-feeding was that they were up against the commercial spirit, and that people who had the temerity to announce the arrival of a baby through the press were assailed through the post by a number of firms selling artificial foods, gripe water, cod-liver oil, and so on. Such propaganda carried on while the mother was just recovering from confinement and was very receptive to influences was bad.

Dr SPINKS, in reply, said with regard to artificial feeding he agreed that it was a matter of teaching doctors and everyone else, not only mothers. Very few people knew anything about babies. Dr Thomson had raised the question of the general practitioner's attitude. That again was a matter of opinion. His own experience *had been a happy* one and he personally had nothing to complain of in Newcastle. The doctor looked at the question from the mother's point of view, and the welfare officers looked at it

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXI

THE TREATMENT OF NIGHT TERRORS IN CHILDREN

Night terrors may be temporary disturbances without significance for the future welfare of the child or may be the sign of a nervous tendency which in itself calls for careful handling in order to avoid psycho-neurotic reactions in later life Except in degree there is no difference between them and nightmares, but the extreme forms cause so much distress to the parents that treatment will be urgently demanded We cannot claim to know definitely any general or specific cause; night terrors are akin to the anxiety dreams of adult psychoneurotics and in some adult cases a recurrent anxiety dream of constant type may exhibit an unbroken continuity with an infantile night terror that possessed the same content

Physical Factors

Physical disorders can stimulate these troubles, though their importance is less than is sometimes supposed. A heavy supper may cause enough discomfort to provoke a nightmare, but patients subject to anxiety dreams find that the time or quantity of the evening meal makes no difference to the symptom So in the child a careful elimination of physical irritation may lead to the disappearance of the terrors, but after adenoids, intestinal parasites, constipation, errors in diet, and all other probable causes of irritation have been removed, there will remain cases in which a source of fear must be presumed to exist in the mind of the child

Sometimes the cries of the child may give a clue which enables the parent to recognise the influence of an actual incident, of a foolish threat, or a terrifying story In such a case the child should be encouraged to talk about the matter, either at the time of the nocturnal disturbance or during the day Modern experience leads to the belief that to prevent nervous trouble, whether as night terrors or in any other form, it is better to encourage the child to talk out a terrifying experience rather than, by a careful avoiding of it, to let the memory remain as an unassimilated mental fragment

The Effect of Excessive Care

There are, however, cases in which fright of any kind can be confidently excluded The child has been carefully secluded from rough knocks of any kind, the nurse is above suspicion, and yet there is displayed an unaccountable nerviness which shows itself particularly in night terrors An only child, or the youngest of several, often shows this sequence, in which it is at first sight impossible to imagine any cause for the nervous manifestations

Certainly there is an inborn tendency to excessive reaction, for quite young babies show wide differences in their reactions to simple stimuli such as sudden noises, but night terrors are matters of later years, and even when we have weighed the factors of inborn temperament and physical stimuli the conceptual content of the terrors demands some hypothesis It is notable that the carefully brought up child is more liable to suffer than another brought up in rougher surroundings, and the investigation of nervous adults has thrown enough light upon the mental processes of the child to enable us to guess at the possible harmful results of excessive care The over-anxious parent tends to stress the emotional aspect of those prohibitions which form so great a part of the education of the child

The teaching of sphincter control and the enforcing of the demands of modesty, for example, may be carried out with an emotional emphasis which easily produces in the child the conception of an unknown something which must not be offended, and here may be one source of the fear that manifests itself as nervousness

Investigation of adults has shown, too, that the childish mind is busied with thoughts about sex and reproduction to a degree which, on account of our loss of memory for our early years, we do not usually suspect. The non-recognition of this fact allows of incidents taking place in presence of the child which may stimulate in him the sense of dread and mystery To share the bedroom of the parents obviously provides the opportunity for such incidents, and here may be found an explanation of the greater liability of the only or youngest child to suffer from night terrors, the birth of a child usually ensures for its predecessor a healthy banishment from the parental bedroom

Apart from this, it is plain that, if parents decide that the curiosity of the child as to sex and reproduction is to be unsatisfied and inevitable questions are to be shelved, the danger of untoward incidents is great, there is nowadays, however, a tendency for these subjects to be handled frankly and unemotionally as soon as they arise and this method may be expected to avoid at least some of the nervous troubles of childhood The principle should be widely applied and we must remember that any subject in which the child scents mystery may become a source of fear Death as much as birth, may become the subject of half-conscious fearful speculations although the child, if allowed to do so, accepts either without any special sense of mystery

The provision of material for fearful speculation may explain why carefully brought up children are subject to night terrors, but these remarks about the possible source of the symptom are to be considered chiefly from the point of view of prevention It is practically out of the question to elicit from the child what that source is terrifying hallucinations may be described but their significance remains hidden as far as investigation of the child can tell us This difficulty need not prevent us from offering to an intelligent child an explanation of the faculty of visualisation and suggesting that the hallucinations should become a source of interest rather than of fear This can do no harm and occasionally succeeds.

A Secondary Factor.

There is a secondary factor in these, as in so many nervous symptoms The nocturnal disturbance obtains for the child the presence of the loving parent, and this satisfaction may help to maintain the symptom To take the sufferer into the parent's bedroom is therefore a step to be avoided, and in every case it should be obvious that the less emotion there is shown the better In fact separation from the parents may sometimes be clearly indicated and their resistance to such a proposal is often a measure of its necessity

On the other hand, the removal of specific causes of fear is justifiable One child may be perturbed by a ray of light, another by darkness, and for another the presence of a particular object may stimulate fear, and adjustments should be made accordingly

Symptomatic Treatment

When attention has been paid to the physical condition of the child and to the material and emotional environment when sympathetic attempts have been made to get the child to talk freely about the nature of the terrifying hallucinations, and when the parents have been properly treated, there will remain cases where we are driven to symptomatic treatment Bromides may then be tried in the usual doses or luminal (pheno-barbital) in quarter-grain doses at night for a child of five

Dr A. F G SPINKS opened the conference by reading a paper on the

Development and Future of Maternity and Child Welfare

He said that the development of the maternity and child welfare movement was probably the most convincing of the many signs of an awakening public interest in public health. It was almost unheard of 25 years ago, and yet though it had been started with all the financial and other disabilities inseparable from voluntary activities it had nevertheless gripped the imagination from the outset and had made for itself a safe and permanent abiding place in national affairs To-day nearly every district—both urban and rural—had its maternity and child welfare scheme, and in England alone there were more than 2000 centres from most of which came reports of rapidly increasing attendances At the Newcastle centres the attendances had increased from 4000 in 1918 to 50,000 in 1926. Dr Spinks traced the development of child welfare work from a centre established in Ghent in 1901. In 1924–25 the total expenditure on maternity and child welfare work in this country amounted to about 1½ million pounds, which represented less than one halfpenny a pound in a national budget of over 800 million pounds—not a large sum to spend on so important an object Preventable ill-health cost the nation many times that amount annually. Those concerned with promoting maternity and child welfare had two main objects in view, first to maintain in good health those who were already healthy—practically every child was healthy at birth—and secondly to improve and increase national efficiency. Thus in principle the movement was essentially preventive and since it dealt with the health of the public at the outset of life it must be the basis of public health Experience had proved that a great deal of the suffering prevalent among young children was due not so much to want of money as to want of knowledge, and unfortunately this want of knowledge prevailed on a vitally important subject from the child s point of view that was its proper food At the present time the bottle-feeding of infants was rampant and unless the craze was checked England would become a bottle-fed nation. There was nothing but teaching at maternity and child welfare centres to save us from such calamity.

The future of the work was assured because it was inconceivable that we should ever be allowed to slip back to the days when infants and young children were allowed to be the victims of undisturbed indifference or mismanagement and needlessly sacrificed Rather did he see maternity and child welfare expanded until it embraced within its benign fold every expectant mother and every child irrespective of class He thought he saw the day coming when we should have health visitors with higher qualifications and perhaps some day, with medical degrees The health and welfare of our mothers and children were national assets, and, as such, ought not to be left to the uncertain caprices of voluntary efforts which—praiseworthy though they were—must always be handicapped by want of money, and by their charitable nature which made them offensive to a large section of the community.

Dr. Spinks envisaged the day when infants hospitals, few in number at present, would be numerous and when many of those in industrial areas would have their own country or seaside convalescent homes The future would also bring a wide extension of open air and natural and artificial sunlight treatment, and unnecessary artificial feeding would be rigidly checked or abolished altogether. A halt must not be called in this work until every preventable calamity that befell women and children had been studied with good effect When that day came there would only be one thing more for the maternity and child welfare movement to do, and that was to pass on the preventive principles upon which it was founded to the general public, so that instead of having as now an army of doctors curing disease we should have an army of doctors preventing it.

In the course of the discussion Dr. MARION MACKENZIE (Leeds) expressed the opinion that maternity hospital nurses should be better trained. They did not know enough about the feeding of infants.

Dr. CHRISTINE THOMSON (Durham) suggested that one of the greatest obstacles to the progress of child welfare work lay not in the difficulties of finance, nor in a lack of public interest, but in the scarcely veiled opposition of the general practitioner The general practitioner regarded the tuberculosis officer or V.D. officer as a specialist, but did not apparently regard the medical welfare officer as a specialist even in infant feeding and frequently would alter the diet of a dyspeptic baby without consulting the welfare officer.

Dr ELIZABETH LANE (Newcastle) spoke of the enormous increase of artificial feeding since she first attended a welfare centre in 1913. One reason was that many mothers did not know how to breast-feed children successfully The result was early evidence of indigestion and a consequent weaning of the baby simply through ignorance A second reason, perhaps equally important was the enormous amount of free food that had been distributed throughout Great Britain in recent years This encouraged the worst type of mother—the young mother, married on the dole and irresponsible living with her own or his people A baby arrived and she was only too anxious to hand it over to its grandmother to be fed with free food, because then she was able to go out and enjoy herself. Weaning often occurred soon after a mother got up when there was a temporary failing of breast milk. Then was the time for the health visitor to give useful advice.

Dr. MARGARET EMSLIE (London) expressed the opinion that one of the chief difficulties in connexion with breast-feeding was that they were up against the commercial spirit and that people who had the temerity to announce the arrival of a baby through the press were assailed through the post by a number of firms selling artificial foods gripe water, cod-liver oil, and so on. Such propaganda carried on while the mother was just recovering from confinement and was very receptive to influences was bad.

Dr. SPINKS in reply, said with regard to artificial feeding he agreed that it was a matter of teaching doctors and everyone else not only mothers Very few people knew anything about babies. Dr Thomson had raised the question of the general practitioner's attitude. That again was a matter of opinion His own experience had been a happy one and he personally had nothing to complain of in Newcastle The doctor looked at the question from the mother's point of view and the welfare officers looked at it

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXI

THE TREATMENT OF NIGHT TERRORS IN CHILDREN

NIGHT terrors may be temporary disturbances without significance for the future welfare of the child or may be the sign of a nervous tendency which in itself calls for careful handling in order to avoid psycho-neurotic reactions in later life Except in degree there is no difference between them and nightmares, but the extreme forms cause so much distress to the parents that treatment will be urgently demanded We cannot claim to know definitely any general or specific cause, night terrors are akin to the anxiety dreams of adult psychoneurotics and in some adult cases a recurrent anxiety dream of constant type may exhibit an unbroken continuity with an infantile night terror that possessed the same content

Physical Factors

Physical disorders can stimulate these troubles, though their importance is less than is sometimes supposed A heavy supper may cause enough discomfort to provoke a nightmare, but patients subject to anxiety dreams find that the time or quantity of the evening meal makes no difference to the symptom So in the child a careful elimination of physical irritation may lead to the disappearance of the terrors, but after adenoids, intestinal parasites, constipation, errors in diet, and all other probable causes of irritation have been removed, there will remain cases in which a source of fear must be presumed to exist in the mind of the child

Sometimes the cries of the child may give a clue which enables the parent to recognise the influence of an actual incident, of a foolish threat, or a terrifying story In such a case the child should be encouraged to talk about the matter, either at the time of the nocturnal disturbance or during the day Modern experience leads to the belief that to prevent nervous trouble, whether as night terrors or in any other form, it is better to encourage the child to talk out a terrifying experience rather than, by a careful avoiding of it, to let the memory remain as an unassimilated mental fragment

The Effect of Excessive Care

There are, however, cases in which fright of any kind can be confidently excluded The child has been carefully secluded from rough knocks of any kind, the nurse is above suspicion, and yet there is displayed an unaccountable nerviness which shows itself particularly in night terrors An only child, or the youngest of several, often shows this sequence, in which it is at first sight impossible to imagine any cause for the nervous manifestations

Certainly there is an inborn tendency to excessive reaction, for quite young babies show wide differences in their reactions to simple stimuli such as sudden noises, but night terrors are matters of later years, and even when we have weighed the factors of inborn temperament and physical stimuli the conceptual content of the terrors demands some hypothesis It is notable that the carefully brought up child is more liable to suffer than another brought up in rougher surroundings, and the investigation of nervous adults has thrown enough light upon the mental processes of the child to enable us to guess at the possible harmful results of excessive care The over-anxious parent tends to stress the emotional aspect of those prohibitions which form so great a part of the education of the child

The teaching of sphincter control and the enforcing of the demands of modesty, for example, may be carried out with an emotional emphasis which easily produces in the child the conception of an unknown something which must not be offended, and here may be one source of the fear that manifests itself as nervousness

Investigation of adults has shown, too, that the childish mind is busied with thoughts about sex and reproduction to a degree which, on account of our loss of memory for our early years, we do not usually suspect The non-recognition of this fact allows of incidents taking place in presence of the child which may stimulate in him the sense of dread and mystery To share the bedroom of the parents obviously provides the opportunity for such incidents, and here may be found an explanation of the greater liability of the only or youngest child to suffer from night terrors; the birth of a child usually ensures for its predecessor a healthy banishment from the parental bedroom

Apart from this, it is plain that, if parents decide that the curiosity of the child as to sex and reproduction is to be unsatisfied and inevitable questions are to be shelved, the danger of untoward incidents is great, there is nowadays, however, a tendency for these subjects to be handled frankly and unemotionally as soon as they arise and this method may be expected to avoid at least some of the nervous troubles of childhood The principle should be widely applied and we must remember that any subject in which the child scents mystery may become a source of fear Death, as much as birth, may become the subject of half-conscious fearful speculations although the child, if allowed to do so, accepts either without any special sense of mystery

The provision of material for fearful speculation may explain why carefully brought up children are subject to night terrors, but these remarks about the possible source of the symptom are to be considered chiefly from the point of view of prevention It is practically out of the question to elicit from the child what that source is terrifying hallucinations may be described but their significance remains hidden as far as investigation of the child can tell us This difficulty need not prevent us from offering to an intelligent child an explanation of the faculty of visualisation and suggesting that the hallucinations should become a source of interest rather than of fear This can do no harm and occasionally succeeds

A Secondary Factor

There is a secondary factor in these, as in so many nervous symptoms The nocturnal disturbance obtains for the child the presence of the loving parent, and this satisfaction may help to maintain the symptom To take the sufferer into the parent's bedroom is therefore a step to be avoided, and in every case it should be obvious that the less emotion there is shown the better In fact, separation from the parents may sometimes be clearly indicated and their resistance to such a proposal is often a measure of its necessity

On the other hand, the removal of specific causes of fear is justifiable One child may be perturbed by a ray of light, another by darkness, and for another the presence of a particular object may stimulate fear, and adjustments should be made accordingly

Symptomatic Treatment

When attention has been paid to the physical condition of the child and to the material and emotional environment, when sympathetic attempts have been made to get the child to talk freely about the nature of the terrifying hallucinations, and when the parents have been properly treated, there will remain cases where we are driven to symptomatic treatment Bromides may then be tried in the usual doses or luminal (pheno-barbital) in quarter-grain doses at night for a child of five

MILLAIS CULPIN, M D Lond, F R C S Eng,
Lecturer on Psychoneuroses, London Hospital
Medical College

could not be excluded. Antenatal care would, however, save large numbers of babies, and they had every reason to believe that by tackling the question of antenatal care a material difference to the rate of maternity mortality and stillbirths could be made. In reply to a question Mr. Evers said he would trust no case entirely to a midwife. No woman should be allowed to go and pick a midwife. She should have to go and pick a doctor and a midwife, and the doctor should then pass the patient as suitable and fit to have labour carried through by the midwife. Antenatal care should not be entrusted to a midwife.

THE LIMITATION OF EXPERT EVIDENCE

(By a Legal Correspondent.)

In the course of a long case which is now before him in the Chancery Division, Mr. Justice Tomlin has had something to say in relation to the calling of expert witnesses. He pointed out that there are very few aspects of life to-day which escape the cunning eye of science, so that in many cases it is open to the parties to introduce a string of experts. He went on to say that if a litigant was left free to call all the evidence possible, it placed a weapon in the hands of persons of large resources. He therefore enunciated a rule, which he proposed to follow in the case before him that only two experts should be called unless there were special circumstances justifying a party in asking that more should be heard. In the present instance—an inquiry into the cause of the flooding of certain mines in South Wales—the plaintiffs' case had taken 26 days, and their two experts had been so fully heard that the issues had become plain. Any rule limiting the amount of expert evidence would be of considerable importance to the medical profession. In the first place, no member of the profession wants to go to court as a witness more often than he can help. Apart from the time he spends in preparing and giving his evidence, he is often compelled to make a long journey to a distant court only to find that the case has been adjourned. In the class of action in which the medical profession has but too good a reason to take an interest—namely, the action for malpraxis—to support a charge of negligence the plaintiff will of necessity rely upon the evidence of practitioners drawn (if possible) from the front of the profession; to refute the charge, the defendant will endeavour to procure the best evidence he can. Those who have the conduct of such litigation know well its cost—indeed the knowledge is made common by subscription lists in the medical journals. Any rule, then, which would limit the number of *mere* expert witnesses on *either* side would necessarily diminish the expense, and the length of the hearing of an action for negligence. It would be so far to the good. But if such a rule endangered the rights of litigants no consideration of convenience or expense will justify it.

Some people, of course may take the view that to place any limitation upon the right to call experts is to unduly restrict the privileges of a litigant. But it is conceived that when the true meaning of "expert evidence" and the proper functions of an expert witness are appreciated, no hardship can occur. As the learned judge took care to point out, a true and accurate knowledge of science and scientific principles may be essential for those who have to apply the law to the facts of particular cases; and although a learned judge may know something of medicine, he cannot hope to do justice unless he is assisted by those who have made it a lifelong study. But there is all the difference in the world between a mere witness and an "expert" witness. The one is called to prove the existence or non-existence of certain facts; the other is there to express an opinion as to what will or is most likely to happen given a certain set of facts. His opinion (if he is a doctor) may not be shared by another practitioner of equal standing in his profession; but it will be for the court to decide which opinion to adopt in determining the issue in the case. In these circumstances it is manifest that an expert must base his opinion upon reasons which he can explain to the judge, and he is the best expert who can best explain himself to one who may have but an inkling of scientific knowledge. Some examples may be interesting.

It was held in an old case (R. *v.* Wright (1821), R. & R. 456) that a witness having medical qualifications may be asked whether such and such appearances proved by other witnesses, are, in his judgment, symptoms of insanity. But a doubt was expressed as to whether such a witness can be asked whether from other testimony given, the act with which the prisoner is charged is in his opinion an act of insanity, that being the very point to be decided by the jury.

It was held in a recent case that the evidence of a medical man was admissible as to the materiality of facts not disclosed in an action on a policy of life assurance (Yorke *v.* Yorkshire Insurance Co., [1918] 1 K.B. 662).

The evidence of experts, however, does not stand much chance if mere theory is opposed to fact. So in a case heard in 1861 (Brock *v.* Kelloch, 30 L.J. Ch. 498), the question was whether a child was or was not born alive. The evidence in the affirmative of the accoucheur, who attended the mother in her confinement, and who was a person of competent skill and integrity was taken to outweigh the contrary opinions of numerous medical men of eminence who were subsequently consulted upon the facts stated.

Viewing the position of an "expert" from this standpoint, it will be seen that the intention is to place a limit, not upon the amount of evidence but upon the amount of "opinion" which is to be voiced upon the scientific result or effect of that evidence. As the rule is to apply equally to plaintiff and defendant there is no reason to apprehend that it will be attended with any serious consequences to the administration of justice. One thing is certain: it will tend to diminish the costs of litigation.

INTERNATIONAL OPHTHALMOLOGICAL CONFERENCE

Early in October last, following on a resolution passed at the general meeting of English-speaking ophthalmologists in July, 1925, a small committee convened by Mr. E. Treacher Collins sent out a general notice to ophthalmological societies and ophthalmologists in all parts of the world, asking them to nominate two delegates from each country to confer on the question of the re-establishment of International congresses and on other matters of International ophthalmological interest. The response to that notice has been widespread and already all the principal countries of the world have indicated their approval of the project, and for the most part have named their delegates.

Arrangements have been made provisionally for the committee to meet at The Hague on Tuesday, July 12th, on the *invitation of the* Netherlands Ophthalmological Society. Mr. Treacher Collins will attend as convener of the conference.

The delegates nominated are:—Argentine: Prof. Dr. Enrique B. Demaria and Prof. Dr. Raul Argañaraz. Austria: Dr. Adalbert Fuchs and Prof. Dr. Josef Meller. Belgium: Dr. Henri Coppez and Dr. Léon Weekers. Bulgaria: Prof. Dr. C. Pascheff and Dr. Slavoff. China: Dr. T. P. Lee. Czecho-Slovakia: Dr. A. Elschnig and Prof. Lese. Denmark: Dr. K. K. K. Lundsgaard and Dr. Chr. F. Bentzen. Finland: Prof. V. Grönholm and Dr. Y. G. Lindberg. France: Dr. Morax and Dr. Terrien. Germany: Herrn Prof. Dr. Axenfeld and Herrn Prof. Dr. Wessely. Great Britain: Sir J. Herbert Parsons and Mr. Leslie Paton. Holland: Prof. Dr. G. F. Rochat and Prof. Dr. J. van der Hoeve. Hungary: Prof. Emile de Grósz and Prof. L. de Blaskovich. Japan: Prof. S. Ishihara and Prof. Oguchi. Norway: Prof. Dr. Hagen and Dr. Malling. Roumania: Dr. C. Pandelescu and Dr. N. Rásvan. Spain: Dr. M. Marquez and Dr. F. Poyales. Sweden: Prof. Fritz Ask and Prof. Albin Dalén. Switzerland: Prof. J. Gonin and Dr. Ernst Pfluger. United States: Dr. G. E. de Schweinitz and Dr. Arnold Knapp.

The following countries have intimated their intention of taking part but have not yet nominated their delegates: Cuba, Italy, Poland, Yugo-Slavia.

from the point of view of the child They said they were not taking patients away from the medical practitioner , they were actually sending him patients Bottle-feeding was increasing in many places not for want of money, but for want of knowledge His experience among the miners who were on the dole and getting little money was that their wives were well able to keep on breast-feeding their babies if they had the knowledge and desire to do so

Infant Feeding.

Dr H **GLEN DAVISON** read a paper on the Feeding and Care of the Premature Infant in the Princess Mary Maternity Hospital He stated that last year they had 165 single premature births and 36 cases of twins, making a total of 201 prematurely born in hospital. Out of these 70 had been stillborn, which left 131 Of these 29 had died and they had been able to send home on the tenth day after birth 102, or 78 per cent of the whole Dr Davison said that they had thrown the teaspoon away as a form of measurement, and he described how they worked on set formulæ which showed just what a prematurely born infant was receiving in protein, fat, sugar, and calories. Whilst they were ready to vary the formula at need it was essential to know at the outset exactly what they were giving the infant and why they were changing from one food to another

Dr **JAMES A STEPHEN** discussed some practical points in infant feeding. Many mothers, he said, complained that the milk left them when they got up out of bed, and he suggested that this might be due to physical causes. Often a mother would get up and sit by the fire for a short time insufficiently clad and catch cold Whilst agreeing that breast-feeding was the form of feeding most to be desired, Dr Stephen stated that a mother's diet of tea and white bread would not provide the wherewithal to feed an infant, and he had had to change his methods in the last year or two on recognising how many mothers were in poor health and anæmic He had had to make up his mind whether a woman was really fit to breast feed her baby with anything like complete results, and he had had to supplement or change the method of feeding altogether, so that largely because of the general condition of the mother he was not so whole-hearted a supporter of breast-feeding as he was Dr Stephen examined the requirements of the under-weight child and the measures that could make milk more digestive to the artificially fed child, showing how lactic-acid milk had outstanding advantages over sweet cow's milk It ought to be possible to prescribe a suitable diet for any child Most of the patent foods were more expensive than cow's milk, but where a mother was careless or ignorant it was often convenient to order those foods Dr Stephen also emphasised the necessity of knowing exactly what was being given to the child Unless they could prescribe a diet that could be easily and accurately made up it was better to turn to the patent food, because mothers would not take the trouble to make anything that was not easy Dr Stephen pointed out that although the patent food manufacturers were in business for commercial purposes, some of them were very interested in welfare work and by scientific research were trying to help it on They should be encouraged in this by the cooperation of the medical profession.

Dr T Y **FINDLAY**, speaking on the clinical value and uses of measuring infants, said one might actually feed a child by its height It had been shown that for every centimetre of its height a normal, healthy child absorbed 14 g of mother's milk So if they wished to know how much to give a child they could measure it and from that calculate its food He did not, however, think this method strictly accurate Dr Findlay discussed the advantages and disadvantages of this and other methods of estimating food require-ments In the subsequent discussion it was suggested that the process outlined by him should be of practical value especially in connexion with observation wards and special clinics where certain infants were difficult to deal with

Mr F C **PYBUS** spoke on pyloric stenosis in infancy chiefly from the surgical standpoint, and discussed the eugenic problem of good parentage as a factor in promoting child welfare

Dr. **MABEL BRODIE** read a paper on

Maternity and Child Welfare Problems in a County Scheme,

in which she stated that most county problems would be solved if sufficient money was available, but to-day it seemed impossible to get enough money to do the work efficiently Health visiting, she thought, would always present difficulties in the counties, because there was nothing that provoked more discussion than the duties of a health visitor—whether district nurses ought to do the health visiting or whether a special officer should be set aside for that purpose Unless the number of health visitors was adequate no following up could be done It was a great advantage to have a health visitor attached to a medical officer attending a centre so that she could see that a mother was carrying out the advice given her Antenatal work was still a problem in most places, and where one had no separate antenatal centre existing it was difficult to get into touch with expectant mothers

Although many county centres were crowded out with infants they had not yet solved the problem of dealing with the pre-school child For this they required more officers and better premises and facilities It did not seem possible to provide separate sessions for these children, partly because in the mining areas particularly the mothers found it difficult to get away more than once a week

Dr F H **MORISON** spoke of the difficulties of carrying on maternity and child welfare work in his county area, where a population of 200,000 was scattered over nearly a million acres Practically all the travelling had to be done by motor ; sometimes a health visitor could only visit one baby in a day, going by train for 20 miles, then bicycling for another six or seven, and walking two or three miles more. A motor dental van had done excellent work all over the rural areas He had anticipated the difficulty in getting hold of the parents and children, but so many came that he had recommended his committee to start another dental van which would act also as a maternity and child welfare clinic That was the only way he could see it possible to deal with such a scattered population over such a huge area

Dr **EUSTACE HILL** said that Dr Brodie had worked in the county of Durham some seven years, and the great advance that had been made in the county were due largely to her enthusiasm , the estimate last year for maternity and child welfare work in the county was nearly £60,000 Unfortunately owing to the coal trouble they had been landed into increased expenditure and, rightly or wrongly, in the feeding of the pre-school child and the nursing mother the sum of over £100,000 had been spent in addition to the normal expenditure Further development was at present not possible, but extension of the nursing services and provision for orthopædic cases were schemes to be undertaken in the future As to the use of district nurses as health visitors, many of the former had been trained to look on their work from the curative rather than from the preventive side. A district nurse often required two or three months' special training on the preventive side of health work before she became efficient, so personally he was strongly in favour of well-qualified health visitors trained as such Speaking of clean milk-supply Dr Hill said he had been amazed at the amount of tubercle bacilli to be found in the milk in country districts Since cows had been found in the byres yielding tuberculous milk a welfare medical officer must be very careful in ordering or recommending unboiled milk for young children

Mr **HARVEY EVERS** communicated common observations on stillbirth and its prevention by antenatal methods Mr Evers was an optimist about antenatal supervision, though in spite of it some babies and mothers would still be lost, since errors

THE MANCHESTER MEDICAL SCHOOL

To the Editor of THE LANCET.

SIR —As the Manchester Medical School is now well over 100 years old it seems desirable that material relating to its history and the history of medicine generally in the town should be collected carefully lest it should be lost The Manchester Medical Society has therefore decided to collect and store in its library all material relating to this history, and we are now writing to appeal for such material.

It is difficult to define what is wanted. but we may make a few suggestions—namely, papers such as minute books or lists of students of the earlier medical schools pictures of these schools diplomas and certificates granted from the schools, reports of prize-givers and inaugural addresses photographs of the medical men of past generations. and letters and diaries written by them The following episode may be used to illustrate the height of our ambition In 1840 in the opening address Thomas Turner. pointing to a small oval table painted green and set on small wooden wheels which stood near him said. ' Excuse me making a digression and directing your attention to that table, mean looking insignificant intrinsically of no value as it is. it was the table of John Hunter This is John Hunter s dissecting table It would seem almost as if the glory of London Anatomy were travelling northward, and that we had arrested it in Manchester It is more than likely that, on that very table, John Hunter prepared some of those splendid specimens which now enrich the walls of the museums of the Royal College of Surgeons Let us now, therefore. that we possess a relic of that great man, be stimulated by the associations it awakens, to pursue the same path that he pursued " Alas this relic has disappeared.

Doubtless the relatives of former leaders of medicine in Manchester are now scattered all over the world but this letter may remind them that the memory of those leaders is still treasured Communications should be made to Dr. Leech the Manchester Medical Society at the University of Manchester

We are Sir. yours faithfully.

ALFRED A MUMFORD. M D.
President of the Manchester Medical Society
E. M BROCKBANK M D. F R C P.
Chairman of the Library Committee

SANATORIUMS AND PUBLIC PREJUDICE

To the Editor of THE LANCET

SIR —It has been my misfortune in the short space of the past four months to have no less than four patients suffering from curable or border-line phthisis discharge themselves from sanatoriums after a stay varying from one week to two months

As taxpayers we contribute towards a huge sum annually to maintain the sanatorium method of dealing with tuberculosis, and as doctors we are responsible for seeing that the money is not wasted I have, therefore. taken some pains to discover why these patients would not stay until discharge and I find that all four of them make two complaints which would seem to be worth making public

(1) They all objected to living with advanced cases. As one man's mother said "It took the heart out of him to have a young chap like him dying in the next bed "

(2) They all complained that they " weren t given no medicine nor treatment nor nothing " and consequently did not see how they could be getting better

To take the second point first surely it would be possible for each patient on arrival to have explained to him the principles of treatment why no medicine would be ordered for him and how he would get better without medicine. and consequently why he should stay until he was cured

The first point I take it is a question of finance. but it seems to me rather straining at the gnat to deny the extra sum required while we swallow the camel of £2,600,000 annually.

I am Sir yours faithfully.
NEVILLE M. GOODMAN.

Lymington, Hants, Feb 14th, 1927

DEATHS UNDER ANÆSTHETICS

To the Editor of THE LANCET

SIR —May I be permitted to give the strongest support in my power to the views expressed by Dr Stanley Sykes in his letter of Feb 12th ? They are chiefly an enforcement of the doctrine which is too often lost sight of—that safety in anæsthesia depends mainly on the anæsthetist The drug and the method are secondary considerations so far as safety is concerned It is not in common talk the gun but the man behind the gun which matters most This truth has never been more forcibly expressed than it was by the Anæsthetics Committee of the British Medical Association years ago That committee stated They are convinced that by far the most important factor in the safe administration of anæsthetics is the experience which has been acquired by the administrator ' There is no such thing as an absolutely safe anæsthetic and only an ignorance of physiology and a lack of clinical experience can lead people to imagine that ether is perfectly safe no matter in what manner or to what extent they use it. It is of course much easier to bring about death with chloroform than it is with ether But I agree absolutely with Dr Sykes that the chances of fatality are reversed if a good anæsthetist gives the chloroform and an inexperienced one the ether

I am Sir yours faithfully.

London, Feb 15th 1927 J. BLOMFIELD.

PULMONARY EMBOLISM FOLLOWING OPERATION.

To the Editor of THE LANCET

SIR —The favourable comments on my paper on Post-Operative Embolism which appeared in your issue of Jan 15th are gratifying. but I should like to comment on some of the questions raised by your correspondents

Mr Lockhart-Mummery suggests that a tight binder round the abdomen is a factor of importance in producing venous stasis by hampering the excursions of the abdominal wall I submit that venous circulation in the abdomen depends not on excursions of its wall but on an alternating rise and fall of intra-abdominal pressure Surely this is most easily obtained by fixing the abdominal wall and contracting and relaxing the diaphragm The difficulty seems to be not that binders are too tight but that however they are applied they cannot adequately support an incision against a rise of intra-abdominal pressure I am glad to see that Mr T B Davies agrees with me on this point

By laying stress on stasis in my paper I did not mean to imply that this was the only factor in the production of thrombosis but simply that it predisposed to it The nature of the second factor remains to be determined Mr Lockhart-Mummery suggests that it is thrombokinase but from the last paragraph of his letter I doubt that he is entirely satisfied that he has a complete answer to the question If the figures in the paper are accepted and he is prepared to accept them on the subject of sepsis any theory as to the nature of the second factor must explain three facts 1 That massive embolism is quite as common in medical as in surgical cases 2 That the liability to embolism increases with age 3 That in any given condition only a very small proportion of cases contracts this complication

BERLIN.

(FROM OUR OWN CORRESPONDENT)

Medical Inspection of Berlin Schools

THE Berlin municipal authorities have decided to appoint henceforth only full-time medical officers to the municipal schools. The number of medical officers will be increased and the number of children for whom each is responsible will be reduced. This is very well from the standpoint of hygienic control, but there is one great drawback to the scheme. Hitherto medical officers have had to do no more than inspect the children and give advice to the parents, but it is now proposed to extend their activities to include attendance in cases of illness, the regulations stating that the medical officer will have to attend a sick child when there is no guarantee of regular attendance by some other medical man. This decision has caused alarm in medical circles, especially amongst those engaged in children's practice. Their work in Berlin was already much limited by the establishment of municipal dispensaries for infants, where the mothers receive medicine and refreshments at low prices, or even free of charge, and where medical attendance is given on a large scale. Medical men whose practice has already suffered so much by the work of the clubs, and in other ways, will again sustain a great loss when the new regulations come into force, and it is to be hoped that the representatives of the profession will do everything in their power to combat them.

Medical Articles in the Lay Press

Prof Julius Schwalbe, the editor of the *Deutsche Medizinische Wochenschrift*, has been drawing attention to the increase of articles on medical subjects in the daily press and to certain nuisances connected with them. As I explained some time ago[1] the daily papers have been in the habit of regularly publishing articles, either by medical members of their staff or by other medical men, sometimes of great scientific renown. Lately there has been discussion in the daily press of difficult scientific matters, like the properties of vitamins and hormones, and the public, getting confused, has been led to consult quacks who are not troubled with such medical controversies. Medical articles in the daily papers, far from combating quackery, as was intended, thus help to increase its influence with laymen. On the other hand, descriptions of symptoms of diseases such as arterio-sclerosis, hypertonia, tuberculosis, and cancer which appear in daily papers, and are read by a large section of the public, are capable both of producing *malades imaginaires* and of alarming really sick people. Prof Schwalbe thinks that the lay press ought to abstain from describing symptoms and discussing diagnostic and therapeutic methods; the only medical articles that should be published are those on prophylaxis and hygiene. He holds that this would incidentally prevent any imputation that the articles are written rather for personal advertisement than public education.

Responsibility of Medical Men for Abuse of Cocaine

A medical man has recently been prosecuted because he prescribed cocaine for healthy people, thus enabling them to get it from a pharmacy. The German Supreme Court in Leipzig in its decision on the case stated that by an international treaty Germany has bound herself to limit the use of opium, morphine, and cocaine to the treatment of diseases and to prohibit it for other purposes. Therefore the import, export, production, and sale of those drugs is allowed only by special licence. Pharmacies do not require a special licence and may dispense these drugs on medical prescriptions, but a medical man prescribing cocaine for other than curative purposes is liable to be punished. Where a chemist has executed the doctor's prescription in good faith he may be held guiltless, but if he has done so knowing that the cocaine is to be used for other than medicinal purposes he is punishable as an accessory.

Supply of Drinking-water to Boats on the Rhine

The water-supply to the Rhine steamers is somewhat defective, according to Dr Klein, chief of the Düsseldorf Institute of Hygiene. It is true, he says, that posters in the ships warn people against drinking Rhine water and recommend the use of drinking-water specially carried on the ships. This water, however, is often kept in tanks standing on deck, the water thus being lukewarm in summer and frozen in winter. The tank itself is often found to contain mud, and river water is used to wash it out. Examination of a tank on board a steamer showed the presence of *Bacillus coli*. Investigation of some of the pumps ashore gave similar results, and strict regulations have now been carried out concerning the quality of drinking water and the cleansing of tanks. A still more efficacious measure is the provision of a tank boat which can steam along the Rhine to supply water to the ships, and a number of these boats are under construction.

Marriage and Mortality

Dr Silbergleit, director of the Berlin Municipal Statistical Office, recently read before the Berlin Society for Public Health a paper on the influence of marriage on mortality. Between the ages of 20 and 30 he said, the death-rate is higher among bachelors than among married men, for women, on the other hand the mortality of the married is 25 per cent higher than that of spinsters, owing to the dangers of pregnancy and childbirth. After the fortieth year of age there is no difference in the death-rate of married and unmarried women. The expectation of life for an unmarried man 25 years of age is 35 years; for a married man it is 41 years, and for a widower 33 years. The expectation of life for an unmarried woman of 25 is 40, for a married woman 42, and for a widow 39 years. For a man marriage thus apparently means an improvement in the chance of living, whilst for women it has not so marked an influence.

Specialism in Germany

Of the 44,000 qualified German medical men not less than 14,000 (or 32·5 per cent) are specialists. Of these 2428 describe themselves as specialists in skin, venereal, and urogenital diseases, and there is thus one specialist in these branches for every 26,000 of the population. There are 1688 specialists for internal diseases, 1661 for nervous and mental diseases, 1536 surgeons 1479 gynæcologists, 1399 aurists and laryngologists 1188 oculists, 975 pædiatrists, and 310 orthopædists. A further 570 combine general surgery with gynæcology and there are 409 specialists for pulmonary diseases, and 239 for gastric affections. The specialists live almost exclusively in the larger towns, except those who are associated with sanatoriums or other institutions in the country.

MEDICAL STUDENTS AND HOSPITAL CARNIVALS—Mr C Grant Robertson Principal of Birmingham University has uttered "a note of warning and misgiving" upon the amount of time consumed by preparation for hospital carnivals. "The annual carnival," he says in his report to the Court of Governors, "threatens to become a dangerous Frankenstein. The cause is admirable, but if it is going for the first four weeks of a term to absorb the full time, thought, and activities of a large body of students, their work and the work of the University will seriously suffer."

LEGACY OF £73,000 TO AN ORPHANAGE—At a sitting of Lancashire Chancery Court on Feb 7th the Vice Chancellor issued a declaration to the effect that the "Liverpool Seamen's Orphanage" and the "Royal Liverpool Seamen's Orphan Institution" are one and the same institution. The funds of the establishment will benefit to the amount of about £73,000 under the will of the late William Reed Pearce, who died last October. The sum was bequeathed to the "Liverpool Seamen's Orphanage," although by Royal Charter the title of the charity was altered in May, 1921, to the Royal Seamen's Orphan Institution.

MANCHESTER ROYAL INFIRMARY —It has been decided that two women and two representatives of the working classes shall be appointed to the board of management

MEMORIAL TO MR HAMILTON DRUMMOND —On Feb 7th a meeting of the subscribers to this memorial was held at the Royal Victoria Infirmary, Newcastle, and it was decided that a bronze medallion portrait should be erected in the infirmary at a cost of not more than £100 and that a scholarship in clinical surgery should be established with the interest on the remainder of the sum subscribed It was stated that £886 had so far been collected, besides £243 contributed towards the special Yeomanry account, and the fund will probably close at £1200 Subscriptions have been limited to five guineas Mr Philip E Noble, Dr R P Ranken Lyle, and Mr G Grey Turner were appointed trustees of the Hamilton Drummond Memorial Fund

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND —At a meeting of the Council held on Feb 10th, Sir Berkeley Moynihan, the President, in the chair, Mr V Warren Low, as executor presented two silver cups bequeathed to the College by the late Mr Herbert William Page, in happy remembrance of his connexion with the College as a member of the Council and of the Court of Examiners The President stated that an election of three Fellows into the Council would take place on Thursday, July 7th, at 10 30 A.M , in the vacancies occasioned by the retirement in rotation of Sir John Bland-Sutton, Sir Cuthbert Wallace, and Mr. W Thelwall Thomas

UNIVERSITY OF BRISTOL —At recent examinations the following candidates were approved —

FINAL EXAMINATION FOR M B , CH B

Part II —Winifred P Brinckman Juan M Camps-Campins, Alan M Critchley, *Thomas F Hewer, Frederic W T. Hughes, †Reginald Jackson, and Edgar R Wide

* With distinction in Pathology

† With distinction in Forensic Medicine and Toxicology

Group I —Helen M Aldwinckle

Part I (*including Forensic Medicine and Toxicology*) —‡ Trevor H Berrill, Bernard J Boulton, Terence A Brand, ‖Ronald M Norman, Eric Southam, ‡Thomas B Wansbrough, and Arthur R Williams

‡ Distinction in Materia Medica, Pharmacy, Pharmacology, and Therapeutics

‖ Distinction in Materia Medica, Pharmacy, Pharmacology and Therapeutics, and Pathology

Part I only —Godfrey D J Ball, Owen J P Bollon, Thomas L Cleave Ronald D Jenkins, Helen B Murgogi, and Ethel M Redman

UNIVERSITY OF BIRMINGHAM —The Council and Senate on Feb 2nd granted permission to licentiates in dental surgery to wear a special gown

HARVEIAN SOCIETY.—At the Paddington Town Hall on Thursday, March 10th, at 8 30 P M., Sir Berkeley Moynihan will deliver the Harveian Lecture His subject will be Diverticula of the Alimentary Canal

OXFORD OPHTHALMOLOGICAL CONGRESS — The seventeenth annual conference will assemble at Keble College, Oxford, on the evening of Wednesday, July 6th, and meetings will be held on July 7th, 8th, and 9th A discussion on the Results of the Operative Treatment of Glaucoma will be opened by Dr William H Wilmer ophthalmologist-in-chief to the Johns Hopkins Hospital, Baltimore and the Doyne Memorial Lecture will be delivered by Prof K K K Lundsgaard, of Copenhagen, his subject being the Pneumococcus in connexion with Ophthalmology. Those who desire to contribute either papers or demonstrations should notify the hon secretary, Mr Bernard Cridland, Salisbury House, Wolverhampton

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —Dr G A. Sutherland will lecture for the Fellowship on Thursday, Feb 24th, on Fits and Faints The lecture will be delivered at 5 P M at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square W , and all members of the medical profession are invited to attend On Feb 23rd, at 5 P M., at the Royal Westminster Ophthalmic Hospital, Mr C L Gimblett will give a lecture on Affections of the Cornea. This lecture will also be free Dr Andrew Wylie will give a special demonstration at the Central London Throat, Nose and Ear Hospital on Feb 24th at 2 P M , members of the profession who wish to attend should notify the hospital secretary (Museum 1539) Beginning on March 7th the Brompton Hospital will hold a week's course, including demonstrations in artificial pneumothorax, X rays, the use of the electrocardiograph The Chelsea Hospital for Women will hold a course from March 14th to 25th and the Royal National Orthopædic Hospital will hold one from March 21st to April 2nd During the same fortnight there will be a late afternoon course, primarily for general practitioners, at the London Temperance Hospital From March 28th to April 9th the Queen's Hospital for Children will hold an all-day course, and from the same date, for two weeks, there will be a series of demonstrations at the Royal Eye Hospital on the Diagnosis and Treatment of Diseases of the Eye The Fellowship arranges practical courses in anæsthetics and also courses in obstetrics Arrangements can be made for clinical assistants in gynæcology Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

Personally I know of no theory that covers these facts but I suspect that the explanation lies in some unknown quality of the blood, more common in old people rendering it more liable to clot than it normally is, the very antithesis, in fact of the equally unknown quality present in hæmophilia Dr Des Vœux and Dr Owen appear to hold very much the same opinion

Dr Owen suggests that this underlying condition may be influenced by influenza and that cases of embolism are more common when this disease is prevalent I can only say that no indication of this is to be derived from the annual figures in my series of cases There is no significant variation in any particular year nor is there proof that embolism is becoming more frequent Again, without a post-mortem one cannot be sure that hæmoptysis in a case of influenza is due to embolism as it is a well-recognised feature of influenzal broncho-pneumonia

I believe that a study of the coagulation of the blood in a large series of elderly surgical patients before operation is performed and trying to detect a difference between those that develop embolism and those that do not, is the most hopeful line of investigation for the future I am, Sir, yours faithfully

Plymouth, Feb 15th 1927 W A LISTER

TREATMENT OF INFLUENZA

To the Editor of THE LANCET

SIR,—I am prompted to write this by the letter of "X" in your issue of Jan 15th, entitled Influenza and Some Gloomy Reflections Several years ago in private practice I worked out a formula which did exceedingly good service in the epidemic of 1918

The remedy consists of a capsule containing quinine hydrochloride, camphora monobromata, hexamethyleneamine, of each two grains, methylene-blue one grain These drugs are well mixed and pounded up together and the capsules filled in this proportion Smaller doses are of course used for children One capsule is given at the onset, followed if necessary in four hours by a second Not more than four should be used in 24 hours, and most of my cases have not required more than three in all, used two in the first 24 hours and one in the second Needless to say the drugs should be given as soon as possible after the onset, and no coal-tar derivatives, salicylic acid products, or other heart depressants should be used Rest in bed, elimination—laxatives and lots of hot tea, freshly made with cream and sugar added, are of course indicated

It is with considerable appreciation of my temerity that I present this formula as I have no series of any thousand cases at the back of it, but merely a possible fifth of this number spread over a number of years, for the reason that after the war I remained in Government service, which, as you know, requires a man to do what is needed to be done, and not that which he desires to do

I am, Sir, yours faithfully,

JULIUS H HURST

2802, Wisconsin avenue N W, Washington, D C,
Feb 4th, 1927

THE NEW ROYAL EAR HOSPITAL —On Feb 9th Mr Neville Chamberlain (Minister of Health) opened the Royal Ear Hospital (Duveen Memorial), which now forms part of University College Hospital In welcoming Mr Chamberlain Mr Geoffrey Duveen, the donor, said that it was hoped that the hospital would be a place where the latest knowledge would be available for practitioners and students who had hitherto been obliged to seek it abroad Mr Chamberlain said that in one year there were more than 50,000 children, or 1 in every 100 children attending school, who were to some extent suffering from defects which required diagnosis and treatment in such a hospital The new hospital is situated in Huntley-street, in close proximity to the main building of University College Hospital, with which it is connected by a subway The staff includes Mr Herbert Tilley Mr G Seccombe Hett, Mr Richard Lake, Dr E A Peters, Mr H A Kisch, and Mr J F O'Malley There is accommodation for about 10 in-patients, including private wards for patients of moderate means

Obituary.

DOUGLAS DOUGLAS-CRAWFORD, M B, C M EDIN, F R C S ENG

AT the age of 60 Mr Douglas Crawford died suddenly at Liverpool on Feb 7th An active man, he had just been granted an extension of his term of office as senior surgeon to the Royal Southern Hospital, and the medical profession in Liverpool will greatly regret his unexpected death He was born and brought up in Liverpool being the son of a doctor who practised there, but he received his medical training in Edinburgh After graduating in 1887 he became a Fellow of the Royal College of Surgeons of England in 1894 meantime spending useful years in study at Dundee, where he was demonstrator in anatomy, and at Berlin, Vienna, and University College, London Thus equipped he came back to Liverpool and started work as a general practitioner, but almost at once devoted his attention to purely surgical work, and was soon elected to the staff of the Stanley Hospital In 1910 he became full surgeon to the Royal Southern Hospital and for nearly three years before his death he was the senior member of its surgical staff Much of his energy was, however, given at one time and another to the Liverpool Dental Hospital and to teaching in the University, in which for many years he was ex-officio lecturer in clinical surgery His instruction made a special appeal to dental students amongst whom his reputation was great He also took an active part in the deliberations of the Faculty of Medicine, where his service on committees and his administrative tact were of great assistance Engaged as he was in a busy practice and in work outside it, Mr Douglas-Crawford did not find time to do much medical writing but he contributed a number of articles to Liverpool journals on chronic prostatitis, on the mechanism by which volvulus is produced, and on other subjects In his own city, however, he is not remembered so much for this side of his activities as for his cheery, breezy personality He often helped his students when they needed help, and he put the interests of his patients before his own

The Council of the University have passed a resolution recognising with gratitude the valuable services which he rendered during 33 years of association with the medical school Memorial services were held at the Royal Southern Hospital and at the Cathedral and the funeral on Feb 10th was attended by several hundred mourners Mr Douglas-Crawford leaves a widow, but no family

FRANCES ELIZABETH HOGGAN, M D ZURICH, M R C P IREL

THE death of Mrs Frances Hoggan, née Morgan, on Feb 9th removes a pioneer among medical women, for Mrs Hoggan was born in 1843 and qualified M D Zurich in 1870, six years before the passing of the Medical Qualifications Act, which threw open the medical profession in England to women She studied also in Prague and Vienna and in 1877 became licentiate and licentiate in midwifery of the King's and Queen's College of Physicians of Ireland in 1877 gaining Membership of the College in 1880 Mrs Hoggan was the third medical woman to practise in London, her predecessors being Miss E Blackwell and Mrs Elizabeth Garrett Anderson, and was physician with Mrs Garrett Anderson to the first hospital in London to be officered by women This hospital began in Crawford-street as St Mary's Dispensary in 1866 and in 1872 developed into the New Hospital for Women with ten beds Most of Mrs Hoggan's contributions to medical literature were made in the 'seventies and included papers in the scientific journals of Italy, France and Germany She wrote on the pathology and therapeutics of membranous dysmenorrhœa in the *Archiv fur Gynacol* in 1876 and several neurological articles, her

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL —Mr and Mrs F Kroyer Kielberg have given Athelstone, their residence at Noctorum, as a convalescent home in connexion with this institution, together with a sum of money for adaptation The home will hold from 30 to 35 children

SKIMMED MILK —The Liverpool Health Committee has asked the medical officer of health and the city analyst to report on condensed skimmed milk imported from the United States It is not allowed to be sold in the United States, but export is allowed to this country The tins bear the notice "Not fit for babies" There is it was stated, a danger that some mothers, for the sake of cheapness, will give it to their children

THE LATE DR C J HARRISON —The death of Dr Charles Joseph Harrison, of Chelsea, occurred on Feb 7th after a rapid illness due to influenza Dr Harrison studied medicine at University College and graduated M B Lond in 1892, proceeding to the M D degree two years later After holding the post of house surgeon at the Victoria Hospital for Children he settled in Chelsea, where he had been in practice for 33 years at the time of his death During the war he acted as surgeon to the Fulham Military Hospital

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY. The President of the year (Dr Gustave Monod) and Council are inviting members and their friends to a conversazione at the rooms of the Medical Society of London on Thursday, March 30th, 8 45 to 11 P M Representatives from France, Germany, Italy, Holland, Belgium, and Czecho-Slovakia have accepted invitations A film showing the annual meeting of the society in Czecho-Slovakia last year will be exhibited and a demonstration will be given of the life-history of silica, showing the effects of hydration and dehydration, and the birth, life, and death of the opal The director of the Wellcome Medical and Historical Museum is lending exhibits to illustrate the history of medical hydrology Members of the medical profession who would like to attend are invited to communicate with Miss Fox, I S M H., 139, Marylebone-road, N W 1

HUNTERIAN SOCIETY —The Hunterian Oration will be delivered at the Cutlers' Hall, Warwick-lane, London, at 9 P.M. on Monday, Feb 28th, by Mr W Girling Ball, on The Value of Modern Methods of Investigation in the Diagnosis and Treatment of Hæmaturia —The annual dinner was held on Feb 10th at the Hotel Victoria The President, Mr A E Mortimer Woolf, took the chair and about 250 Fellows and guests were present, including the Lord Chief Justice and the Lord Mayor and Lady Mayoress of London. The toast of The Hunterian Society was proposed by the Lord Chief Justice, and the President briefly and wittily responded Mr J E H Roberts proposed The Guests, the reply being divided between Sir Francis Newbolt (England), Mr Hugh Edwards, M P. (Wales), and Dr H C Cameron (Scotland) The musical part of the programme was given by Mrs Westerman and Mr J Batten The proceedings ended with a hearty vote of thanks to the two honorary secretaries

R.A.M C SCHOLARSHIPS AT CHELTENHAM COLLEGE Six years ago the Aldershot R A M C Fund Committee endowed four scholarships one to be competed for annually at Cheltenham College The Foundation is for the benefit of the sons of all officers of the R A.M C The first two scholars who entered Cheltenham under this scheme have just left, having taken fifth and sixth places respectively on the Woolwich and Sandhurst lists of December last Both boys have been awarded prize cadetships into those institutions on account of their high positions on the lists It is not generally known that the sons of all medical officers—Regular, Special Reserve, Territorial and Temporary—who died of wounds or disease during the Great War are primarily eligible to compete for these scholarships, and that in default of candidates under this category, the sons of all living medical officers serving or retired come within the scope of this Foundation In the event of any boy falling short of scholarship standard money grants are sanctioned in suitable cases, and there are several boys receiving these benefits at the College now The value of the scholarships is approximately £50 per annum tenable for four to five years, a purely classical or modern education being given at the desire of the parents or guardians

Messrs Kelvin, Bottomley, and Baird, who manufacture the K B B apparatus for ultra-violet light therapy, have opened new showrooms at Imperial House Regent-street, London, W 1

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Poor-law Consolidation

IN the House of Lords, on Wednesday, Feb 9th, a Government measure consolidating enactments relating to the relief of the poor was introduced and read a first time

New Bills

In the House of Lords on Tuesday, Feb 15th, Viscount ASTOR presented the Education (Employment of Children and Young Persons) Bill, and the Bastardy Bill, both of which were read a first time

Private Members' Bills

Among the Bills presented by private Members in the House of Commons on Friday, Feb 11th, were the following —

Mr WOOD To amend certain enactments relating to mental defectives —Mr RUSSELL To secure the registration of optical practitioners and to regulate the practice of sight-testing and for purposes incidental thereto —Mr TINKER To consolidate with amendments the enactments relating to factories and for purposes connected therewith —Mrs PHILIPSON To provide for the registration and inspection of nursing homes and for purposes connected therewith —Mr BARCLAY-HARVEY To amend the Midwives (Scotland) Act, 1915, and to provide for the registration and inspection of maternity homes and for purposes connected therewith —Sir H LUCAS-TOOTH To extend maternity benefits in cases of miscarriage and for purposes connected therewith

Vivisection of Dogs

In the House of Commons on Monday, Feb 14th, Sir R GOWER presented a Bill to prohibit the vivisection of dogs

Workmen's Compensation

On the same date Mr F HALL presented a Bill to amend the law relating to workmen's compensation

HOUSE OF COMMONS

THURSDAY, FEB 10TH

Government and Spahlinger Treatment

Sir CHARLES CAYZER asked the Minister of Health whether his department was at present in communication with Mr Spahlinger in regard to his treatment, and, if so whether he would state the present position of any such negotiations —Mr N CHAMBERLAIN replied I am not, at present, in communication with Mr Spahlinger, but it has been publicly stated on my behalf that the offer made to him to arrange for a scientific investigation in this country of his method of treatment as soon as the necessary materials are forthcoming, is still open

Approved Societies and Dental Fees

Sir THOMAS DAVIES asked the Minister of Health whether he was aware that the majority of approved societies, embracing over 90 per cent of the population entitled to dental benefit under the National Health Insurance Act had accepted the new scale of fees for dental service under that Act, which scale was negotiated and agreed between representative men in approved society organisations and representative men in dental professional organisations and whether, in these circumstances, he would take such steps as might be necessary to secure that insured persons who were members of the few approved societies whose officials were opposing such agreed scale should not be deprived of dental benefit through a refusal by such officials to consider estimates based by dentists upon such scale or through inability on the part of the member to find a dentist willing to do work at lower fees than those so agreed —Mr N CHAMBERLAIN replied The position with regard to the new scale of fees for dental service is as stated by the hon Member As regards the latter part of the question I could not regard it as satisfactory that any approved society which has included dental benefit in its scheme of additional benefits should make such arrangements as resulted in its insured members being unable to obtain satisfactory dental treatment with reasonable freedom of choice of dentist and I shall not hesitate to take the necessary steps to deal with any such case that may be brought to my notice

Housing Statistics

Mr HANNON asked the Minister of Health whether he had statistics available showing the number of houses erected under the Housing Acts in the years 1924, 1925, Mr H Edgar Smithers announces that he is compiling a directory entitled "Who's Who in the Nursing World" Further information may be had from him at 139, High Holborn, London, W C 1

THE Cambridge University Press will publish early next month a book by Dr Bernard Hart entitled "Psychopathology Its Development and its Place in Medicine" Most of this book is taken up by the Goulstonian Lectures delivered before the Royal College of Physicians in 1926 (THE LANCET, 1926, i, 585 and 700) Dr Hart describes the development of psychopathology and critically reviews the chief tenets of the various schools

MEDICO-LEGAL SOCIETY—An ordinary meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W 1, on Thursday, Feb 24th, at 8 30 P M, when a paper will be read by Dr F J McCann on Some Cases of Medico-legal Interest in the Practice of Gynæcology A discussion will follow Members may introduce guests on production of a member's private card

ROYAL SANITARY INSTITUTE—The Henry Saxon Snell Prize will in 1927 consist of 50 guineas and the medal of the institute, and is offered for an essay on Sanitary Accommodation, Appliances and Fittings for Hotels and Flats, with suggestions as to proper placing, arrangement, ventilation and lighting, particularly where there are no external walls in which windows can be placed Details may be had from the Secretary of the institute 90, Buckingham Palace-road, London, S W 1

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX—At a meeting to be held at the Royal Institute of British Architects on Feb 23rd Mr G F Barwick will speak on the compilation of a directory of sources of specialised information which has been going on under his direction for eight months Cards of invitation can be had from the Secretary of the Association 38, Bloomsbury-square, London, W C 1

LIVERPOOL POST-GRADUATE COURSE IN CARDIOLOGY

A special two weeks' post-graduate course will be given at the Liverpool and District Hospital for Diseases of the Heart from March 7th Early application should be sent to Prof J M Beattie at the hospital, entry being limited to 20

RETIREMENT OF IRISH MEDICAL OFFICIAL—The retirement is announced of Dr C J MacCormack, who has been for many years medical member of the General Prisons Board of Ireland and Inspector of Reformatory and Industrial Schools Before his appointment to the Prisons Board Dr MacCormack was for some years a medical inspector of the Local Government Board, he had previously practised in Athlone His colleagues and the office staff of the Prisons Board met last week to make him a presentation on his retirement

STERILISATION OF DEFECTIVES—The Surrey County Council recently appointed a subcommittee to consider a resolution passed by the Worcestershire County Council urging the Government to take compulsory measures for preventing the spread of mental deficiency, by sterilisation, by compulsory segregation, or by other measures The subcommittee has reported that the weight of available evidence is to the effect that, apart from certain cases due to acquired injury or disease of the brain, heredity is probably the biggest factor in the causation of mental defect, but although the defect often occurs in the child of a defective parent, a defective is more often the child of a parent who has transmitted an ancestral strain of tainted stock without personal signs of mental abnormality An analysis of family histories of 500 recent consecutive cases in Surrey shows that in only 25 per cent was one parent in any way abnormal mentally, and in four cases only—i e, 0 08 per cent—were both parents defective (some of these, perhaps, not being certifiable under the Act) It would appear that if every defective now existing were to be sterilised, says the subcommittee's report, the result a generation hence would be insignificant "It is generally recognised," the report goes on, "that sterilisation does not materially affect moral propensities which have already been acquired, and a sense of security might even lead to increased dissemination of venereal disease It is important to remember that cases which are subject to be dealt with under the Act mostly require segregation (which would equally prevent procreation) because of failure to be self-supporting or some other antisocial factor which would not be remedied by sterilisation, and institutional training and care would still be required for such cases" The Surrey County Council, having received this report, has decided not to ask the Government to promote legislation for the sterilisation of defectives

SOUTH LONDON HOSPITAL FOR WOMEN AND CHILDREN—The out-patient department of this hospital is described as "deplorable, cramped, and dilapidated," and a new one will cost £65,000, towards which King Edward's Fund has promised £3250

DINNER TO DR LILY BAKER—A dinner has been given at Bristol to celebrate the appointment of Miss Lily Baker to the honorary staff of Bristol Royal Infirmary Except at the Royal Free Hospital this is the first time that a medical woman has been made a member of the full staff of a general teaching hospital in the British Isles Dr Baker is in charge of the antenatal department

FIRST-AID AND THE WIRELESS—The Dublin Broadcasting Station has included in its programme in recent weeks a series of lectures on first-aid and ambulance work An inaugural lecture, describing the work of the St John Ambulance Brigade, was delivered by Sir John Lumsden, M D, Commissioner for Ireland, and has been followed week by week by lectures from other teachers. Each lecture lasts 15 minutes

ST ANDREW'S HOSPITAL, DOLLIS HILL—It is stated that the want of accommodation at this hospital has become a serious problem, and that £30,000 is required at once for the provision of additional beds, the opening of a children's ward, and a home for the nurses and staff The sum of £4600 has so far been contributed The hospital was opened in 1913 for the professional and middle classes, and although contributions are asked from patients who can afford it, no patient has been refused solely on the ground that he could not pay a fee

LONDON ASSOCIATION OF MEDICAL WOMEN—At a meeting held on Jan 25th, the President, Miss Elizabeth Bolton, in the chair, Dr Margaret Dobbie-Bateman gave an address on Some Aspects of Industrial Medicine She discussed industrial medicine chiefly as it applied a particular organisation of medical practice to meet a particular social service Factory medical officers, she pointed out, must be distinguished from certifying surgeons The latter were invested with certain statutory powers and were required to fulfil certain statutory duties, whereas the factory medical officers were the officials of the industrial organisations in which they worked, their powers being purely advisory Their business, from the staff managerial point of view, was (1) to prevent the engagement of people unable by reason of physical disability to do the work required of them, (2) to prevent absence of workers and, therefore, loss of work—through sickness and (3) to prevent loss of work through lowered physical efficiency of employees at work Restated from the point of view of the workers—and on this restatement Dr Dobbie-Bateman laid great stress—the medical officer's duty was to restrain people from undertaking work they were unable to do and to keep them in a full and happy capacity at work The first aim was met by a preliminary medical examination of candidates for employment Between those completely fit and those totally unfit was a large class whose applications had to be considered Standards of fitness for employment in industry need not be as rigid as standards for acceptance in the army It was a pity that anyone should be excluded from helping to produce if he was likely to be able to do so It was often possible to allocate suitable work to a candidate who would not be capable of work in certain departments, or to recommend treatment after which the candidate became fit for any work A knowledge of the industrial processes was, therefore, necessary to the medical officer Unfortunately, certain people still had an objection to a compulsory medical examination, and Dr Dobbie-Bateman was now trying the experiment of a voluntary medical examination for applicants over the age of 16, though for younger people she was convinced that compulsory examination was necessary in their own interests For the prevention of absenteeism it was essential (1) to examine the staff returning from sick leave, if possible before they rejoined their departments, and (2) to rule that the only pass-out given to workers leaving their posts for reasons of health should be given by the medical officer The first rule prevented people from returning to work before they were fit, whilst the knowledge that a visit had to be paid to a medical officer acted as a deterrent to those whose headaches tended to occur on the Tuesday after Bank Holiday The industrial medical officer was also called on for first aid, for advice as to lighting, heating, and ventilation, for the determination of optimum periods of rest, and for the superintendence of canteen arrangements There was urgent need of a dental scheme in connexion with industrial medicine and an ophthalmological service would also be of value Finally, research into industrial dermatitis and industrial fatigue should be actively pursued best use of the staff at its disposal , and I cannot see my way to interfere with the Governor's exercise and his discretion in a matter of this kind

Education of Physically Defective Children

Major Hills asked the President of the Board of Education what was being done by the Board for the education of children of school age who were suffering from more than one defect , what was the number of such children of the various types of double or triple defect in England and Wales , and, as these children were found in small numbers all over the country and were not numerous in any particular area, could any steps be taken for the formation of a joint committee of the local education authorities for large areas to provide suitable institutions for the instruction of such children —The Duchess of Atholl replied This matter is receiving careful consideration My right hon friend has been furnished with certain particulars regarding the education and care of children of this type, but he is afraid that complete statistics are not available In so far as the children are mentally defective they fall within the purview of the special committee which is now investigating the question of the provision which should be made for mentally defective children, and my right hon friend is not at present in a position to make a statement on the subject

Lead Poisoning in the Potteries

Major Hills asked the Home Secretary how many cases of lead poisoning in the potteries occurred in factories using low-solubility glazes since the regulations of 1913, which gave special exemption to such factories —Sir W Joynson-Hicks replied During the 11 years 1916–26, there were 67 such cases out of a total of 351, but in 60 of these there had been previous employment, often for many years, in factories using raw lead glazes I am glad to tell my hon friend that the incidence of lead poisoning in potteries of this class is to be the subject of a special investigation by one of the medical inspectors, and the investigation will be proceeded with at an early date

Public Expenditure on Medical Treatment

Mr Robert Morrison asked the Minister of Health if he would state the expenditure for each year from 1923 upon provision and treatment for tuberculosis maternity and child welfare, venereal disease, and welfare of the blind respectively —Mr Chamberlain replied It is presumed that the question relates to expenditure out of moneys provided by Parliament The amounts of such expenditure in England and Wales for the financial years 1923–24 to 1925–26 in respect of the services mentioned in the question were as follows —

—	1923–24	1924–25	1925–26
	£	£	£
Maternity and child welfare	791,000	814,000	897,000
Treatment of tuberculosis	1,337,000	1,430,000	1,547,000
Grants towards provision of sanatoria	87,000	15,000	19 000
Treatment of venereal diseases	303 000	298,000	307,000
Welfare of the blind	83,000	95,000	104,000

Tuesday, Feb 15th

Use of Poisons and Bacteria in War

Mr James Hudson asked the Prime Minister whether, in view of the recommendation of the League of Nations Disarmament Commission, that all subsidies, both to private and official laboratories promoting research in poison gases, be abolished, the British Government was prepared to give a lead in this matter and whether the Government was prepared, in accordance with the further recommendation of the same commission, to introduce legislation forbidding any one, civilian or military, to perform exercises in the use of poisons and bacteria —Mr Baldwin replied Until such time as a definite assurance can be obtained that all Powers are willing to adopt measures of prohibition in regard to poisons and bacteria, His Majesty's Government must take steps to be in a position to defend itself against such attacks In regard to the second part of the question, so long as our nationals might be exposed to attacks of this nature, it is the bounden duty of His Majesty's Government to take steps to provide protection for them

Deaths from Tetanus in London Hospitals

Mr Day asked the Minister of Health the number of persons who had died in London hospitals as the result of lockjaw following dog-bites during 12 months to the last convenient date.—Sir Kingsley Wood replied No deaths certified as due to tetanus following dog-bites took place in any London hospital during 1925 No subsequent figures are as yet available

Grade A Milk Licences

Mr Wells asked the Minister of Health if he would reconsider the charges at present made for licences, as set out in the Fourth Schedule of the Milk and Dairies Order, 1923, with a view to their reduction, and so assist those agriculturists desirous of providing the public with milk of Grade A quality —Sir Kingsley Wood replied · The charges made by local authorities for Grade A milk licences are designed to cover the cost of supervision and bacteriological examination, and, on the information at present before him, my right hon friend does not consider that they could properly be reduced

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 5TH, 1927

Notifications —The following cases of infectious disease were notified during the week : Small-pox 547 (last week 532); scarlet fever, 1287 ; diphtheria, 988 ; enteric fever, 32 , pneumonia, 3198 (last week 2618); puerperal fever, 36 ; puerperal pyrexia, 130 , cerebrospinal fever, 17 , acute poliomyelitis, 13 ; acute polioencephalitis, 3 ; encephalitis lethargica, 49 ; dysentery, 16 ; ophthalmia neonatorum, 131 There was no case of cholera, plague, or typhus fever notified during the week

One case of small-pox was notified from Portsmouth C B , one further case from Stockport C B , and none from Essex. The remaining cases were distributed, as last week, amongst the following counties · Derbyshire 20, Durham 340, Lancashire 4, Northumberland 12, Nottinghamshire 1, Yorkshire 168

Deaths —In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 43 (1) from measles, 11 (5) from scarlet fever, 89 (26) from whooping-cough, 51 (12) from diphtheria, 42 (9) from diarrhœa and enteritis under 2 years, and 818 (215) from influenza The figures in parentheses are those for London itself The influenza deaths for the last six weeks have thus been 86, 173, 326, 470 725, and 818, while 759 is the figure notified for the week ending Feb 12th, the deaths in London being 159

DONATIONS AND BEQUESTS

Under the will of the late Mr Robert Allison, J P , of Paisley, subject to his wife's life interest, the testator left among other bequests, £2000 to the Orphan Homes of Scotland and Consumptive Sanatorium, Bridge of Weir , £1000 each to the Paisley Eye Infirmary, the Glasgow Eye Infirmary, the Royal Glasgow Asylum for the Blind, the Glasgow Deaf and Dumb Institution, the Glasgow Samaritan Hospital for Women, the Glasgow Cancer Hospital, the Royal Hospital for Sick Children , £500 each to the Paisley and District Mission to the Deaf and Dumb, the Glasgow Hospital and Dispensary for Diseases of the Ear, the Glasgow Hospital for Skin Diseases the Mission to the Outdoor Blind for Glasgow and the West of Scotland, the West of Scotland Convalescent Homes, Dunoon, and the East Park Home for Infirm Children —Mrs Blanche Murray, of Manchester-square, W , and Taigmount, Stanley, Perth, left £5000 to the Perth Royal Infirmary, to endow a bed in memory of her husband, if not already given by her or her children.—The Royal Manchester Children's Hospital, Pendlebury has received £1000 from the executors of the late Miss Mary Scott Monat to endow a cot, £350 from the Manchester Civic Week Executive Committee, and £170 from the sale of silver paper —Mr William Wright, Kirkcaldy Fife, left besides other bequests £1000 to Kirkcaldy Hospital, and £500 each to several institutions including the Queen Victoria Nursing Association Kirkcaldy —Dr Patrick John Smith Nicoll, M D , J P , of Stratford, London, E , left £5000 upon trust for the provision of a maternity home for the poor of Rhynie, Aberdeenshire, and district, £5000 (part of which for the endowment of a bed) to Queen Mary's Hospital for the East End —Mr Bernhard Baron has given £10 000 to the Royal Westminster Ophthalmic Hospital for the building fund —Mrs Annie Jane Raine Sandsend near Whitby late of Sunderland left £2000 to the Greenbank Hospital, Darlington, for the endowment of two beds in memory of her husband and herself, and £1000 to the New Whitby War Memorial Hospital —By will the late Mr.

and 1926, and also the numbers which had been erected in the same years without subsidy —Mr N CHAMBERLAIN replied The following table gives the information desired by the hon Member —

Year	Number of houses erected—		
	With subsidy under the Housing Acts during the year ended in—		Without subsidy during the year ended in September
	December	September	
1924	52,730	36,459	73,032
1925	99,497	92,291	66,735
1926	144,619	131,895	65,689

Condemned Houses

Mr. ALBERY asked the Minister of Health how many condemned houses in England, Scotland, and Wales were occupied in December, 1924, and in December, 1926 —Mr N. CHAMBERLAIN replied Statistics are not available for England and Wales giving the information desired by the hon Member According to the annual reports of medical officers of health 12,722 houses were reported during the year 1924 as unfit for human habitation Similar information for 1926 is not yet available As regards Scotland I would suggest that a similar question should be addressed to the Secretary of State

Cost of Pauper Lunatics

Mr DENNISON asked the Minister of Health the average weekly cost per head of a pauper lunatic and an indoor pauper for the last two complete years ending March 31st —Mr N CHAMBERLAIN replied It is estimated that, excluding the cost of buildings and loan charges, which on the average may be put at between 6*s* and 7*s* per week, the average weekly cost per head of persons maintained in institutions for lunatics at the cost of the guardians was, for the year ended March 31st, 1924, 22*s* 2¾*d*, and, for the year ended March 31st, 1925, 21*s* 3¼*d* The average weekly cost of a person maintained in a Poor-law institution in England and Wales, including the cost of buildings and loan charges was 25*s* 5*d* for the year 1923–24, and 27*s* 1½*d*. for the year 1924–25

The Purity of Imported Milk

Lieut -Col ACLAND-TROYTE asked the Minister of Health what steps he was taking to ensure that milk imported from foreign countries was produced under conditions as good as those laid down in the Milk and Dairies Order, and how he proposed to protect the public against imported milk which was not produced under proper conditions —Mr CHAMBERLAIN replied The Public Health (Imported Milk) Regulations, which I made at the same time as the Milk and Dairies Order, require all milk imported from foreign countries to be in such a condition that on a sample being taken it shall be found to contain not more than 100,000 bacteria per cubic centimetre and to be free from tubercle bacilli The Regulations are enforced by means of a requirement that an importer must be registered with the port or riparian sanitary authority and may be struck off the register if he imports milk which does not comply with the provisions of the Regulations I may perhaps add that the amount of milk which is imported into England and Wales is practically negligible

Pensioners and Reopening of War Wounds

Mr ROBINSON asked the Minister of Pensions if he would take the necessary action to enable men who were suffering from wounds inflicted in the great war to claim pension should the wound break down or reopen after the expiry of seven years from the termination of active service in the war —Major TRYON replied I would refer the hon Member to the reply which I gave on Feb 11th, 1926, in which I stated that in the case of an old wound which has broken down more than seven years after discharge, and required surgical treatment, I had issued instructions that immediate steps should be taken to provide such treatment The experience of the past year shows that such cases are, for the most part, restored by treatment, but if in any such case the man is found after treatment to be seriously incapacitated consideration is given to the making of an appropriate grant

Rehousing of Tenants of Condemned Houses

Mr ALBERY asked the Minister of Health if he would impress on local authorities the desirability of utilising the 1924 Building Act primarily to rehouse those living in condemned houses, and if he was aware that this was not being generally done —Mr CHAMBERLAIN replied I have already, in a circular recently issued to local authorities, urged them to devote themselves specially to the provision of the type of houses capable of being let at rents within the means of the less well-paid workers I do not think it is practicable for local authorities in letting new houses to limit themselves in the first instance to the class to which my hon friend refers, but I believe it is the general practice to give weight to the claims of those living in condemned houses

FRIDAY, FEB 11TH

Rating Reform

Mr FENBY, on behalf of the Liberal Party, moved the following amendment to the Address in reply to the Gracious Speech from the Throne —

> "But this House deplores that the Government do not propose to bring forward measures for the relief of the local rates, by which expenditure in many districts has risen to almost unbearable dimensions, and which now so impedes the revival of our industrial and agricultural prosperity, and for the reduction of rating on improvements by placing a fair share of the burden upon the monopoly values in the urban districts which have been created by these communities"

The burden of the rates was, he said, shown by the fact that while in 1900 the amount of rates per head of the population per annum was £1 6*s* 11*d*, it was £1 15*s* 4*d* in 1910, £1 19*s* 6*d* in 1915, £2 16*s* 4*d*. in 1920, and £3 14*s* 7½*d* in 1924 He hoped that the Minister of Health would give the House a definite promise that he was prepared to frame legislation to deal with this pressing evil

Mr G THORNE seconded the amendment

Mr NEVILLE CHAMBERLAIN (Minister of Health) said it was generally agreed that the burden of rates in the urban districts was increasing, and was weighing very heavily on industry, but he failed to see how that was going to be remedied by the amendment What was really wanted in his view was a new arrangement of national and local taxation, one which would have the effect of spreading over the national area some part of the burden which was now directly concentrated unduly on local spots There must be three stages if they were to deal with it on sound and permanent lines Seeing that an essential feature was capacity to pay, the first necessity was that they should have some sort of uniformity of valuation throughout the country The Government had taken the first step in passing the Rating and Valuation Act The second step, he believed, was to be found in the concentration of financial control in any area in one authority The reform of the Poor-law system under which this concentration took place and under which one authority would be able to keep under its own control and within its own purview the whole financial aspect of public expenditure in that area, was the second step The third step to follow on, or it might even be to accompany it, would consist in the actual formula for the adjustment of the relations between national and local expenditure It was possible, now that the announcement had been made of the Government's hopes to introduce a new measure of Poor-law reform in the autumn, to speak with greater precision on this matter than he had done previously He did not say that it would be possible between now and the autumn to define the financial arrangements which would cover the whole field of service, and which would be satisfactory to all concerned What he did say, however, was that they would spend the intervening time in exploring still further ideas to which they had already given prolonged consideration They would consult the local authorities concerned on their proposals, and if and when they were able to produce a complete scheme he thought they would have advanced towards solving the problem of the necessitous areas which had troubled and baffled so many Governments in the past

After further debate,

The amendment was defeated by 244 votes to 88—majority against, 156

MONDAY, FEB 14TH

Medical Service in Gold Coast Colony

Sir COOPER RAWSON asked the Secretary of State for the Colonies (1) from what date it was proposed to appoint a native doctor to succeed a European doctor at Dunkwa, Gold Coast Colony, where there were over 40 European residents, including women, and, seeing that the nearest European doctors to Dunkwa were at Sekondi and Kumasi 6½ and 1½ hours away respectively, with only one train a day in each case, would he appoint a European doctor at Dunkwa, and (2) whether, seeing that a European doctor had been put in charge of a native hospital at Elmina, he would say why he or some other European doctor should not be appointed to Dunkwa —Mr AMERY replied It is the policy of His Majesty's Government that natives of West Africa who are qualified medical men and otherwise suitable for public employment should be employed in the Government service in West Africa Three African medical officers are employed in the Gold Coast out of a total medical staff of 67 My hon friend will of course understand that it must rest with the Colonial Government to make the

MEDICAL SOCIETY OF LONDON, 11, Chandos street, Cavendish square, W

Monday, Feb 21st —9 P M, Mr Donald J Armour The Surgery of the Spinal Cord and Its Membranes (First Lettsomian lecture)

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos street, Cavendish square, W

Friday, Feb 25th —8 30 P M Papers will be read by Capt F Doble and Dr A Cambell on Urethritis as seen through the Urethroscope, with demonstration of the instrument, and a discussion will follow.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, London, W C

Wednesday, Feb 23rd —8 P M, Ordinary meeting Mr Francis H Carr (President of the Society of Chemical Industry) Insulin and its Manufacture

THE MEDICO-LEGAL SOCIETY

Thursday, Feb 24th —8 30 P M (at 11, Chandos street, Cavendish-square, W) Dr F J McCann Some Cases of Medico Legal Interest in the Practice of Gynæcology, to be followed by a discussion

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W

Monday, Feb 21st, to Saturday, Feb 26th —Fellowship of Medicine Special lecture at the Medical Society, 11, Chandos street, Cavendish square, W, at 5 P M, on Thurs, Dr G A Sutherland Fits and Faints Open to all members of the medical profession without fee —Central London Throat, Nose, and Ear Hospital, Gray's Inn road W C Special clinical surgery demonstration on Feb 24th, at 2 P M, by Dr Andrew Wylie Open to all members of the medical profession without fee, but those wishing to attend are asked to notify the hospital secretary (Museum 1539) —Royal Westminster Ophthalmic Hospital, Charing Cross, W C Special lecture at 5 P M on Feb 23rd, Mr C L Gimblett Affections of the Cornea —London Lock Hospital, Dean street, W Special course in Venereal Diseases Clinical work daily and special lectures —National Hospital, Queen square, W C Special course in Neurology Daily instruction and special lectures —Further information from the Secretary

NORTH-EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

Monday, Feb 21st —10 A M, Surgical Clinic 2 P M, Medical Cases in the Wards 2 30 P M to 5 P M, Medical, Surgical, and Gynæcological Clinics Operations

Tuesday —2 30 P M to 5 P M, Medical, Surgical, Throat, Nose, and Ear Clinics Operations

Wednesday —2 30 P M to 5 P M, Medical, Skin, and Eye Clinics Operations

Thursday —11 30 A M, Dental Clinic 2 30 P M to 5 P M, Medical, Surgical, and Ear, Nose, and Throat Clinics Operations

Friday —10 30 A M, Throat, Nose, and Ear Clinics 2 30 P M to 5 P M, Surgical, Medical, and Children's Diseases Clinics Operations

On Monday, Feb 21st, and Wednesday Feb 23rd, there will be special demonstrations of Medical Cases and Eye Cases by Dr J B Alexander and Mr N B B Fleming respectively

ROYAL NORTHERN HOSPITAL POST-GRADUATE INTENSIVE COURSE

Monday, Feb 21st —2 15 P M, Dr W R Reynell The Treatment of the Anxiety-Neuroses 3 15 P.M, Mr Kenneth M Walker The Treatment of Prostatic Obstruction

Tuesday —2 15 P M, Dr J W McNee Some Diseases of the Biliary Tract 3 15 P M, Mr A M Zamora Carcinoma of the Larynx

Wednesday —2 15 P M, Dr H C Semon Notes on the Diagnosis of Skin Diseases 3 15 P M, Mr J B Hunter The Surgery of the Chest

Thursday —2 15 P M, Dr Bruce Williamson Drugs in Disease of the Heart 3 15 P M, Mr C S Lane Roberts On Obstructed Labour

Friday —2 15 P M, Mr F D Saner Cancer of Rectum 3 15 P M, Mr C L Gimblett Some Points of General Interest in Eye Diseases

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W

Monday, Feb 21st.—10 A M, Mr MacDonald Genito Urinary Operations 2 P M, Mr Addison Surgical Wards 2 P M, Dr Ironside Medical Out patients

Tuesday —10 A M, Medical Registrar Clinical Methods 12 noon, Dr Burrell Chest Cases 2 P M, Mr Vlasto Throat, Nose, and Ear Department

Wednesday —10 A M, Dr Owen Medical Diseases of Children 2 P M, Dr Scott Pinchin Medical Out-patients 2 30 P M, Mr Armour Surgical Wards

Thursday —10 A M, Dr Stewart Neurological Department 12 noon, Mr Simmonds Demonstration of Fractures 4 P M, Sir Henry Simson Meddlesome Midwifery

Friday —11 A M, Dr Pritchard Modern Methods in Medicine 2 P M, Mr Sinclair Surgical Out patients

Saturday —9 30 A M, Dr Burnford Bacterial Therapy

Daily —10 A M to 5 P M, Operations, Medical, Surgical, Special, Out-patient Departments (Saturdays 10 A M to 1 P M)

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W C

Thursday, Feb 24th —4 P M, Dr Shires X Ray Diagnosis

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY POST-GRADUATE LECTURES

Wednesday, Feb 23rd —5 30 P M, Mr S A Riddett Some Lesions of the Soft Tissues of the Mouth in Children fortune in the practice of his profession in the sparsely settled colonies The colonists themselves, as has already been indicated, were so actively engaged in the struggle for existence, and in securing the bare necessities of life—surrounded as they were by unfriendly natives and equally unfriendly neighbours—that little time was left for the consideration of medical education

The Psalmist's conception of "the pestilence that walketh in darkness and the arrow that flieth by day" was to the poor harassed colonist no mere figure of speech but a stern reality The ravages of the oft-recurring pestilences—smallpox, yellow fever, malaria, diphtheria, &c —were far deadlier than the Red Man's arrows or the bullets of the French The pages of fiction contain nothing more thrilling than the exploits of such sterling characters as the pioneers and pathfinders of those early days, many of whom were doctors Ephraim McDowell, Benjamin Dudley, Nathan Smith, Daniel Drake, and hosts of others whose names are known to posterity, or unknown, as the case may be What could be more tragic than the melancholy records of the many and varied pestilences that, from time to time, sweeping over the different settlements with irresistible fury, wiped many of them completely out of existence? What could be more sublime than the courage and the fortitude with which those early settlers, with dogged determination, stood up against oft-recurring dangers, difficulties, and disaster that would have terrified and utterly discouraged hearts cast in a less heroic mould?

The Philadelphia Medical College and its Founders

During the latter half of the eighteenth century a new era began to dawn on the medical profession in the colonies Young men graduated in the arts in the young American colleges, men of real ability and filled with scientific enthusiasm, began to flock to Europe in considerable numbers, and after receiving the best training that her institutions afforded and experiencing the stimulating influence of her great teachers returned to practise their profession in the New World Then began the forward movement in medical education and practical achievement which has characterised the American school of medicine down to the present day

In 1762, William Shippen, jun, one of these young educated Americans just mentioned, returned to his native city, Philadelphia, where he was joined three years later by John Morgan, also just returned from a season of foreign study Morgan, like Shippen, had enjoyed the privilege of working under John Hunter for an extended period Both had been resident students in his household and both had taken their medical degrees at Edinburgh, spending five years each in foreign study Shortly after his return, Morgan delivered a public lecture on the Institution of Medical Schools in America. This lecture so impressed the trustees of the University of Pennsylvania that they at once decided to establish a medical department, and asked Morgan to take the chair of medicine and Shippen that of surgery A few months later Adam Kuhn and Benjamin Rush, both educated abroad, were added to the faculty Thus was established in 1765 the first school of medicine in America, with its founder, John Morgan, and its first professor of surgery, William Shippen, jun, both former pupils of and confessedly much influenced by their common teacher, John Hunter To Shippen belongs the credit for having first suggested to Morgan the idea of a medical school, though it was the latter who was chiefly instrumental in bringing about its final consummation

Shippen and the Hunter Household

William Shippen, jun, one of the founders and first professor of surgery and anatomy in the Philadelphia Medical College, took his A B degree at Princeton He then studied for a season in his father's office in Philadelphia Later he went to London and became a pupil of the Hunters

Through the kindness of my friend, Dr J. Hall Pleasants, of Baltimore I have had the opportunity to examine, in the original, his diary written while a member of the Hunter household The first reference in the diary to his association with Mr Hunter is that of Monday, Oct 1st, 1759 "Busy in packing my things for Mr Hunter's In the evening attended Dr Hunter's first lecture Tuesday, 2nd Moved my trunk to Mr Hunter's. Dr Hunter's lecture at 5 till 7 30 Wednesday, 3rd at 5 Dr Hunter's lecture Lay for the first night at Mr. Hunter's" From this on there is a daily note as to how he occupied his time It was mostly spent in the dissecting room For instance on Oct 6th 'Spent the day in the dissecting room till 5 Dr Hunter's lecture till 7 30 Bed at 10 30 talking anatomy with Mr Hunter from supper" It will be observed that distinction is made between "Doctor" and "Mr" Hunter This is noted throughout the diary On the 16th "Dissected till 5 Lecture till 7 30 Chatted till 10 with Mr Hunter upon anatomical points Bedded at 10 30" On the 25th "At home all day dissecting and injecting Lecture at 5 till 7 Read Pott on the fistula lachrymalis till 11 Bed"

That his time, however, was not spent wholly in dissecting and injecting and discussing anatomy with Mr. Hunter is shown by numerous references to visits to the theatre, dances, and other diversions For instance, one entry states, after a busy day "Attended a new farce, entitled 'High Life Below Stairs', very good and appropriate to the times" On Nov 7th this entry "Rose at 7 Mr. Hunter dissecting muscles for lecture Went to see patient under my care After lecture went to St Bartholomew's Hospital and saw the neatest operation for bubonocele that I ever saw, by Mr Pott, a very clever, neat surgeon" A characteristically American comment by an embryo surgeon upon the work of a master On the 16th "Dissected all the remainder of the day Lecture at 5 till 6 Talked anatomically with J Hunter Bed at 10" This entry, "dissected all day," appears very constantly in the diary Evidently Mr Hunter kept his pupils busily occupied On the 13th (December) "Waited upon Mr Hunter while he injected a body for blood-vessels" Tuesday, the 18th "Dissected all day Lecture at four Went to a ball in city after lecture, danced with Miss Knox, an agreeable lady and good dancer Thirty-five ladies genteelly dressed Bed at two" One wonders what his comment on present-day styles of feminine attire would have been! Saturday, the 22nd. Evening at home with Mr Hunter who generally lives out of town" The diary contains much that is of interest, but these extracts will suffice to show the general character of its contents

A Liberal Education

Very soon after his return from Europe Shippen began his course of lectures in anatomy, which was the beginning of the Medical Department of the University of Pennsylvania Two degrees were offered by this first School of Medicine, the Bachelor's and the Doctor's Degree in Physic The first class, consisting of ten men, received the Bachelor's Degree on June 21st, 1768 In a circular prepared by John Morgan, the founder, after describing the requirements necessary for the two degrees, he goes on to say "The above scheme of a medical education is upon as extensive and liberal a plan as in any of the most respectable European seminaries, and the utmost care is taken to render the degrees real marks of honor and distinguished learning and ability" He significantly adds "A good medical education is here looked upon as not the least useful part of science" We cannot but admire the spirit exhibited by these eager and enthusiastic young men and their courage and foresight in planning upon such broad and liberal lines the infant institution founded by them, as shown in the requirement of a previous liberal education before undertaking the study of medicine, and the establishment of a curriculum of medical study comparing favourably with that of the Old World institutions It was patterned largely after Edinburgh, of which both founders were graduates

Morgan had attained great prominence as a medical teacher when the Medical School was forced, by the outbreak of the War of the Revolution, to close its doors He then became director-general and chief physician of the American Army on Washington's staff During his rather short and active life he was a power in medical circles in the colonies, but he was not interested in surgery and contributed nothing to it, so he drops out of our story

Later Medical Schools

In 1767, two years after the establishment of the Philadelphia School, a second school of medicine was organised in New York. Samuel Bard was the leader in the foundation of the Medical School of King's College, the forerunner of the College of Physicians and Surgeons, now Columbia University, and was its first professor of the theory and practice of physic Among others associated with him in this enterprise were John Jones and Peter Middleton, of whom we shall have more to say later Bard was second only to Benjamin Rush in distinction among American physicians of his day, and stands in the same paternal relation to the establishment of the first medical school in New York, that Morgan and Shippen do to that founded two years earlier in Philadelphia A full medical faculty of six professors was named, and the first course of lectures given in 1768–69, at the end of which the Degree of Bachelor of Medicine was given to two young men, and in the following year the degree of M D, the first time that this degree was awarded in America

Reference should also be made to Harvard Medical School and its founder, John Warren While Warren did not enjoy the advantages of a foreign education and training, still, as stated by Mumford, he undoubtedly belongs, as does his more famous son, in that group of American surgeons who received their inspiration from John Hunter After the close of the Revolutionary War, in which he had served with distinction as a hospital surgeon, he began a course of lectures which gradually developed into the Medical

Notes, Comments, and Abstracts.

THE INFLUENCE OF JOHN HUNTER UPON EARLY AMERICAN SURGERY

Being the Hunterian Lecture delivered before the Hunterian Society at the Mansion House, London, on Jan 17th, 1927,

By John M T Finney, MD,

PROFESSOR OF CLINICAL SURGERY AT JOHNS HOPKINS HOSPITAL, BALTIMORE, SOMETIME PRESIDENT OF THE AMERICAN COLLEGE OF SURGEONS AND CHIEF CONSULTANT IN SURGERY TO THE AMERICAN EXPEDITIONARY FORCE

[Prof Finney began by referring to the kinship, mutual interest, and common purpose which bind the two great English-speaking nations and went on to pay an eloquent tribute to the achievements of John Hunter, whom he described as the founder of modern scientific surgery He proceeded as follows —]

In order to comprehend more clearly the deep and lasting influence that Hunter and his pupils have exerted upon surgical thought and action in the United States of America it is necessary to have as a background some knowledge of the history and development of early American surgery

There seems to be little definitely known, beyond their names, regarding those who practised medicine in the infancy of the colonies What little is available, however, is of great interest, for those pioneers laid well the foundations for future medical progress in America It is worthy of note that many of them seem to have been possessed of more than ordinary ability and advanced medical learning, such as it was in their day In the various centres, of which Charleston, Philadelphia, New York, and Boston were perhaps the chief, and which, for 300 years, comprised practically all of the area occupied by the settlers, we find here and there individuals some with medical degrees, chiefly from Edinburgh, but more without and with little or no special training, who were using their skill and the little medical knowledge they possessed, for the benefit of their fellows, with a surprising measure of success

Since educated men among the colonists were at a premium, it was not uncommon to find several offices combined in the same individual, exhibiting a versatility unusual in this day One of the most common combinations, especially in New England, perhaps was that of clergyman and doctor For instance, the earliest practitioner of medicine in Massachusetts was Samuel Fuller, one of the passengers on the *Mayflower* in 1620, and a deacon of the church at Plymouth, who is continually referred to in the ancient records as "surgeon of the settlement" Although he had no medical degree he served as medical adviser to all the colonies about that part of Massachusetts Bay The records contain abundant evidence to show that the good deacon exercised spiritual powers of no mean order, as well as skill in the management of physical ills, for, aided, no doubt, by prayer and the *vis medicatrix Naturæ*, it is related of him that he ' met with great success in his practice"

The earlier records also contain instances of medical men attaining high rank in civil and political life Several governors are numbered among them, of which perhaps the most conspicuous example is the younger Winthrop, who was Governor of Connecticut, a man of such distinguished scientific attainment as to have been one of the founders of the Royal Society Three of the earlier presidents of Harvard University, and the first president of Princeton, were doctor-preachers

In reviewing thus hastily the status of medicine in the American colonies in the seventeenth century, it should be borne in mind that they stretched in a narrow strip from what is now Florida to Massachusetts, bordered upon the one hand by the Atlantic Ocean, and on the other by the unexplored wilderness inhabited by wild men and wild beasts They were a series of more or less isolated settlements, representing various nationalities and interests, with little or no cohesion; they were torn by political and religious strife, the communication between the various groups being irregular and difficult, their educational facilities were most meagre and undeveloped In this period, while a few names stand out in the medical profession, a small but not insignificant beginning was made of medicine in the New World It was all that could reasonably be expected, perhaps, considering the conditions which obtained at that time, and it served as a necessary basis for better things to come

The Eighteenth Century

The first half of the eighteenth century marked little advancement in American medicine The reason for this may well have been the very unsettled social and political conditions in which the colonies still found themselves Starting with Queen Anne's War, in 1702, wars and rumours of war with Spain, France, and their Indian neighbours, finally culminating in 1776 in the American Revolution, kept the colonists in such an agitated state of mind as to militate strongly against the development of scientific pursuits Several significant influences, however, were beginning to make themselves felt While everything medical yet remained provincial to a degree, and almost entire dependence was placed upon Europe for instruction and advancement along this line, still men were beginning to see that interchange of ideas was necessary for progress, and feeble attempts were apparent here and there to adapt old methods to new conditions

The earlier American medical writings were of little merit and were largely descriptive in character, dealing with personal observation of new flora of the wilderness and their therapeutic properties, with reports of cases, or with personal experiences with epidemics, of which small-pox was the most deadly Sydney Smith's caustic criticism with regard to the character and number of American medical contributions up to this time was, unfortunately, quite pertinent The name of one man stands out as perhaps the most prominent in the earlier years of the century, that of Zabdiel Boylston, of Boston He was the son of Dr Thomas Boylston, an Englishman with an Oxford degree, who had come out in 1635 The younger Boylston studied medicine with his father, as it was before the days of colonial medical schools He is noted chiefly for the brave stand that he took in the controversy over inoculation for small pox. He had the courage to inoculate, in 1721, his own son, a lad of 13, and two of his house servants This occurrence took place just six weeks after Lady Mary Wortley Montague's famous inoculation séance and, of course, in entire ignorance of it For this he suffered severe persecution for a time, but finally triumphed after demonstrating to both the profession and the laity the great value of inoculation Subsequently he was officially invited to come to London to demonstrate his method Here he was received by Royalty, and was made a member of the Royal Society—the first native American to be so honoured

Pioneers of Medical Education in America

But the eighteenth century in its second generation produced another group of half a dozen medical men of sufficient note to warrant brief mention These all, with a single exception, Thomas Cadwallader, of Philadelphia, came from the south, of which at that time Charleston was the social and commercial centre Cadwallader was educated abroad and was a pupil of Cheselden On his return from London, as was so frequently done by those who, like himself, had had the benefit of foreign study, he established a class in practical anatomy and dissection He appreciated the value of adequate medical education and was among the first to advocate the establishment of a medical school in the colonies The other five, all Scotsmen, with one exception, were John Lining John Moultrie, Lionel Chalmers, Alexander Garden, and William Bull, the last named being American born These men were all of a type which would have left its impress anywhere Educated chiefly in Edinburgh they were among the first to transplant Old World ideas and ideals to the New They introduced the European culture and scientific point of view that was to be a little later brought over in greater volume by the continually increasing number of young, native-born, but foreign-taught, Americans Heretofore, the only local medical training available had been through men educated in foreign countries, who had come out either as colonists or as army surgeons, and had remained permanently This crude haphazard method sufficed for a time, until the founding of Harvard in 1636, and the other colleges thereafter in fairly rapid succession The young men educated there, with higher ideals, were not satisfied with a picked-up (so to speak) medical course They looked, therefore, across the sea to the centres where adequate instruction was to be found

It has been noted with some surprise, by historians of the colonial period in America, that medicine, as a separate branch of education, had received so little consideration during the first century after the settlement of the country While, as is characteristic of English colonisation everywhere, the school-house had accompanied the pioneer, and institutions of learning more or less advanced had been early established, yet it was not until after the first half of the eighteenth century had passed that any attempt had been made to establish a medical college, and up to the time of the Revolution less than half a hundred young men had been graduated therefrom It will at once be evident that many causes were active in bringing about this condition of affairs The chief of these, perhaps, was the backward state of the profession everywhere, even in Europe In the new colonies the hardy pioneer stood less in need of medical attention than others less actively engaged Little opportunity was offered to the medical man for either fame or fortune in the practice of his profession in the sparsely settled colonies The colonists themselves, as has already been indicated, were so actively engaged in the struggle for existence, and in securing the bare necessities of life—surrounded as they were by unfriendly natives and equally unfriendly neighbours—that little time was left for the consideration of medical education

The Psalmist's conception of "the pestilence that walketh in darkness and the arrow that flieth by day" was to the poor harassed colonist no mere figure of speech but a stern reality The ravages of the oft-recurring pestilences—small-pox, yellow fever, malaria, diphtheria, &c —were far deadlier than the Red Man's arrows or the bullets of the French The pages of fiction contain nothing more thrilling than the exploits of such sterling characters as the pioneers and pathfinders of those early days, many of whom were doctors Ephraim McDowell, Benjamin Dudley, Nathan Smith, Daniel Drake, and hosts of others whose names are known to posterity, or unknown, as the case may be What could be more tragic than the melancholy records of the many and varied pestilences that, from time to time, sweeping over the different settlements with irresistible fury, wiped many of them completely out of existence? What could be more sublime than the courage and the fortitude with which those early settlers, with dogged determination, stood up against oft-recurring dangers, difficulties, and disaster that would have terrified and utterly discouraged hearts cast in a less heroic mould?

The Philadelphia Medical College and its Founders

During the latter half of the eighteenth century a new era began to dawn on the medical profession in the colonies Young men graduated in the arts in the young American colleges, men of real ability and filled with scientific enthusiasm, began to flock to Europe in considerable numbers, and after receiving the best training that her institutions afforded and experiencing the stimulating influence of her great teachers returned to practise their profession in the New World Then began the forward movement in medical education and practical achievement which has characterised the American school of medicine down to the present day

In 1762, William Shippen, jun one of these young educated Americans just mentioned, returned to his native city, Philadelphia, where he was joined three years later by John Morgan, also just returned from a season of foreign study Morgan, like Shippen, had enjoyed the privilege of working under John Hunter for an extended period Both had been resident students in his household and both had taken their medical degrees at Edinburgh, spending five years each in foreign study Shortly after his return, Morgan delivered a public lecture on the Institution of Medical Schools in America. This lecture so impressed the trustees of the University of Pennsylvania that they at once decided to establish a medical department and asked Morgan to take the chair of medicine and Shippen that of surgery A few months later Adam Kuhn and Benjamin Rush, both educated abroad were added to the faculty Thus was established in 1765 the first school of medicine in America, with its founder, John Morgan, and its first professor of surgery, William Shippen, jun, both former pupils of and confessedly much influenced by their common teacher, John Hunter To Shippen belongs the credit for having first suggested to Morgan the idea of a medical school, though it was the latter who was chiefly instrumental in bringing about its final consummation

Shippen and the Hunter Household

William Shippen, jun., one of the founders and first professor of surgery and anatomy in the Philadelphia Medical College, took his A B degree at Princeton He then studied for a season in his father's office in Philadelphia. Later he went to London and became a pupil of the Hunters

Through the kindness of my friend, Dr J Hall Pleasants, of Baltimore I have had the opportunity to examine in the original, his diary written while a member of the Hunter household The first reference in the diary to his association with Mr Hunter is that of Monday, Oct 1st, 1759 "Busy in packing my things for Mr Hunter's In the evening attended Dr Hunter's first lecture Tuesday 2nd Moved my trunk to Mr Hunter's . Notes, Comments, and Abstracts.

THE INFLUENCE OF JOHN HUNTER UPON EARLY AMERICAN SURGERY.

Being the Hunterian Lecture delivered before the Hunterian Society at the Mansion House, London, on Jan 17th, 1927,

By John M T Finney, M D,

PROFESSOR OF CLINICAL SURGERY AT JOHNS HOPKINS HOSPITAL, BALTIMORE, SOMETIME PRESIDENT OF THE AMERICAN COLLEGE OF SURGEONS AND CHIEF CONSULTANT IN SURGERY TO THE AMERICAN EXPEDITIONARY FORCE

[Prof Finney began by referring to the kinship, mutual interest, and common purpose which bind the two great English-speaking nations and went on to pay an eloquent tribute to the achievements of John Hunter, whom he described as the founder of modern scientific surgery. He proceeded as follows —]

In order to comprehend more clearly the deep and lasting influence that Hunter and his pupils have exerted upon surgical thought and action in the United States of America it is necessary to have as a background some knowledge of the history and development of early American surgery.

There seems to be little definitely known, beyond their names, regarding those who practised medicine in the infancy of the colonies. What little is available, however, is of great interest, for those pioneers laid well the foundations for future medical progress in America. It is worthy of note that many of them seem to have been possessed of more than ordinary ability and advanced medical learning, such as it was in their day. In the various centres, of which Charleston, Philadelphia, New York, and Boston were perhaps the chief, and which, for 300 years, comprised practically all of the area occupied by the settlers, we find here and there individuals, some with medical degrees, chiefly from Edinburgh, but more without and with little or no special training, who were using their skill and the little medical knowledge they possessed, for the benefit of their fellows, with a surprising measure of success.

Since educated men among the colonists were at a premium, it was not uncommon to find several offices combined in the same individual, exhibiting a versatility unusual in this day. One of the most common combinations, especially in New England, perhaps, was that of clergyman and doctor. For instance, the earliest practitioner of medicine in Massachusetts was Samuel Fuller, one of the passengers on the *Mayflower* in 1620, and a deacon of the church at Plymouth who is continually referred to in the ancient records as "surgeon of the settlement." Although he had no medical degree he served as medical adviser to all the colonies about that part of Massachusetts Bay. The records contain abundant evidence to show that the good deacon exercised spiritual powers of no mean order, as well as skill in the management of physical ills, for, aided, no doubt, by prayer and the *vis medicatrix Naturæ*, it is related of him that he "met with great success in his practice."

The earlier records also contain instances of medical men attaining high rank in civil and political life. Several governors are numbered among them, of which perhaps the most conspicuous example is the younger Winthrop, who was Governor of Connecticut, a man of such distinguished scientific attainment as to have been one of the founders of the Royal Society. Three of the earlier presidents of Harvard University, and the first president of Princeton, were doctor-preachers.

In reviewing thus hastily the status of medicine in the American colonies in the seventeenth century, it should be borne in mind that they stretched in a narrow strip from what is now Florida to Massachusetts, bordered upon the one hand by the Atlantic Ocean, and on the other by the unexplored wilderness inhabited by wild men and wild beasts. They were a series of more or less isolated settlements, representing various nationalities and interests, with little or no cohesion, they were torn by political and religious strife, the communication between the various groups being irregular and difficult, their educational facilities were most meagre and undeveloped. In this period, while a few names stand out in the medical profession, a small but not insignificant beginning was made of medicine in the New World. It was all that could reasonably be expected, perhaps, considering the conditions which obtained at that time, and it served as a necessary basis for better things to come.

The Eighteenth Century

The first half of the eighteenth century marked little advancement in American medicine. The reason for this may well have been the very unsettled social and political conditions in which the colonies still found themselves. Starting with Queen Anne's War, in 1702, wars and rumours of war with Spain, France, and their Indian neighbours, finally culminating in 1776 in the American Revolution, kept the colonists in such an agitated state of mind as to militate strongly against the development of scientific pursuits. Several significant influences, however, were beginning to make themselves felt. While everything medical yet remained provincial to a degree, and almost entire dependence was placed upon Europe for instruction and advancement along this line, still men were beginning to see that interchange of ideas was necessary for progress, and feeble attempts were apparent here and there to adapt old methods to new conditions.

The earlier American medical writings were of little merit and were largely descriptive in character, dealing with personal observation of new flora of the wilderness and their therapeutic properties, with reports of cases, or with personal experiences with epidemics, of which small-pox was the most deadly. Sydney Smith's caustic criticism with regard to the character and number of American medical contributions up to this time was, unfortunately, quite pertinent. The name of one man stands out as perhaps the most prominent in the earlier years of the century, that of Zabdiel Boylston, of Boston. He was the son of Dr Thomas Boylston, an Englishman with an Oxford degree, who had come out in 1635. The younger Boylston studied medicine with his father, as it was before the days of colonial medical schools. He is noted chiefly for the brave stand that he took in the controversy over inoculation for small-pox. He had the courage to inoculate, in 1721, his own son, a lad of 13, and two of his house servants. This occurrence took place just six weeks after Lady Mary Wortley Montague's famous inoculation séance and, of course, in entire ignorance of it. For this he suffered severe persecution for a time, but finally triumphed after demonstrating to both the profession and the laity the great value of inoculation. Subsequently he was officially invited to come to London to demonstrate his method. Here he was received by Royalty, and was made a member of the Royal Society—the first native American to be so honoured.

Pioneers of Medical Education in America

But the eighteenth century in its second generation produced another group of half a dozen medical men of sufficient note to warrant brief mention. These all, with a single exception, Thomas Cadwallader, of Philadelphia, came from the south, of which at that time Charleston was the social and commercial centre. Cadwallader was educated abroad and was a pupil of Cheselden. On his return from London, as was so frequently done by those who, like himself, had had the benefit of foreign study, he established a class in practical anatomy and dissection. He appreciated the value of adequate medical education and was among the first to advocate the establishment of a medical school in the colonies. The other five, all Scotsmen, with one exception, were John Lining, John Moultrie, Lionel Chalmers, Alexander Garden, and William Bull, the last named being American born. These men were all of a type which would have left its impress anywhere. Educated chiefly in Edinburgh they were among the first to transplant Old World ideas and ideals to the New. They introduced the European culture and scientific point of view that was to be a little later brought over in greater volume by the continually increasing number of young, native-born, but foreign-taught, Americans. Heretofore, the only local medical training available had been through men educated in foreign countries, who had come out either as colonists or as army surgeons, and had remained permanently. This crude haphazard method sufficed for a time, until the founding of Harvard in 1636, and the other colleges thereafter in fairly rapid succession. The young men educated there, with higher ideals, were not satisfied with a picked-up (so to speak) medical course. They looked, therefore, across the sea to the centres where adequate instruction was to be found.

It has been noted with some surprise, by historians of the colonial period in America, that medicine, as a separate branch of education, had received so little consideration during the first century after the settlement of the country. While, as is characteristic of English colonisation everywhere, the school-house had accompanied the pioneer, and institutions of learning more or less advanced had been early established, yet it was not until after the first half of the eighteenth century had passed that any attempt had been made to establish a medical college, and up to the time of the Revolution less than half a hundred young men had been graduated therefrom. It will at once be evident that many causes were active in bringing about this condition of affairs. The chief of these, perhaps, was the backward state of the profession everywhere, even in Europe. In the new colonies the hardy pioneer stood less in need of medical attention than others less actively engaged. Little opportunity was offered to the medical man for either fame or

Lettsomian Lecture

ON THE

SURGERY OF THE SPINAL CORD AND ITS MEMBRANES.

Being the First Lettsomian Lecture in 1926. delivered before the Medical Society of London on Feb. 21st 1927,

BY DONALD ARMOUR, C.M.G., M.B. TORONTO, F.R.C.S. ENG., M.R.C.P. LOND.,

SENIOR SURGEON TO THE WEST LONDON HOSPITAL AND SURGEON TO THE NATIONAL HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

IT is somewhat to be wondered at that this subject has not been dealt with before in these lectures, for it is one around which controversy has raged from time to time with some bitterness—controversy finally laid to rest, at any rate as far as concerns the subject in its broadest aspects, by the introduction of Listerian surgery and by the great progress made in recent years in neurological diagnosis and localisation

HISTORY.

It is true that the discussions for and against operation were limited at first to cases of injury of the spine, but there can be little doubt that operation was advocated, and almost certainly practised, from the earliest times Hippocrates writing in his "Treatise on Articulations," advises that when bloodless methods have failed to reduce a fracture—dislocation of the spine, the body should be opened and the vertebra replaced from before backwards by the hand in the abdomen He adds naively, however, "that this is only possible in the dead, and not on the living" The successors of Hippocrates. on the contrary, advised that surgical intervention should be directed to the vertebral arches, which were considered to be the cause of the medullary compression

In the seventh century Paulus Aegneta urged that, when there is compression of the spinal cord an incision should be carried down to the bone and an attempt made to raise the compressing fragment This, he adds, should be done only after warning the patient of the danger of the operation

In 1526 Fabricius Hildanus proposed that when extension and coaptation were unsuccessful, the following operation should be performed An incision is made down to the spinous processes of the vertebræ and prolonged upon their right and left sides, to expose the laminæ. (An exact description, it will be noticed, of the modern operative approach.) Then the fragments are to be seized with forceps and the luxation reduced while simultaneous extension is made upon the spine to aid the reduction He advises operation as soon as possible after the accident

In 1545 Ambroise Paré urged surgeons to greater boldness and advised the removal where possible, of the splinters or pieces of bone which had been driven in and were compressing the cord and nerves Vigier in 1559, Heister in 1739 and James in 1745 all advised the same procedure Heister says · ' But to offer the patient no assistance because we despair would seem cruel and uncharitable therefore we must try our skill though our efforts should be in vain; in order to which the surgeon must lay bare the fractured vertebræ with a scalpel and replace or else remove such fragments as injured the spinal marrow."

Louis in 1762 performed what was the nearest approach to a formal resection of the spine upon M de Villedon Captain in the Regiment of Vaubecourt, who was paralysed from a gunshot wound of the back, received at the battle of Aménébourg. Fragments of bone were removed and the patient finally recovered sufficiently to be able to walk Louis also speaks of ' the indication for the trephine. even without fracture, to give exit to blood or matter, or even to prevent suppuration in some cases of fracture" He made a sketch of the operation suggested Chopart and Desault (1771) speak of it as a very simple thing to trephine between the spinous and transverse processes to give issue to effused fluids, or to elevate or remove pieces of bone which may wound the cord They were supported in this by Benjamin Bell 1796

The Beginning of Modern Surgical Practice

But these counsels remained for the most part purely theoretical until 1814 just a year before the death of the founder of this Society, when the younger Cline performed the first formal operation for the removal of a depressed vertebral arch. In the clinical lecture which he delivered afterwards to explain the reasons which had induced him to perform this operation, and the grounds upon which he hoped for success, he said that he considered that in fracture with displacement of the vertebræ, which compressed the spinal cord, the cord was under precisely the same circumstances as the brain with a depressed fracture of the skull, and that the indications were the same in both cases—i e removal of the compression He considered that the only reasonable objection to the operation was the inability to decide before operation whether the cord was simply compressed, either by bone or effused blood, or partially or completely severed.

Cline's operation. although the patient died. attracted widespread attention and gave rise to vehement discussion as to its justification This discussion often degenerating into bitter and virulent personalities, went on for many years Astley Cooper, Benjamin Bell, Tyrrell, South, and others upholding the operation, while Charles Bell. John Bell Benjamin Brodie, and others violently opposed it Brodie thought that under the most auspicious circumstances more harm than good would result from the operation But Astley Cooper urged that it might occasionally be successful and alluded to the opponents to the operation as "blockheads" To this Charles Bell retorted :—

> "We must submit to hear many strange proposals for the improvement of our profession in the present day from young men ambitious of notice, but that a man of Sir Astley's years and station should talk as he has done before students, and give them his authority for laying a patient upon his belly, and by incisions laying bare the bones of the spine, breaking up these bones, and exposing the spinal marrow itself, exceeds all belief"

And this coming from the leading neurologist of the day. doubtless had a great influence in retarding the development of spinal surgery.

Failures and Successes

For some years only an occasional operation. almost invariably unsuccessful, was reported from time to time, though one by a Welsh surgeon named Edwards was reported in 1838 as being successful. But the details are meagre. So unsuccessful were the results of the operation that Malgaigne in his "Treatise on Fractures and Luxations" (1847) joined the ranks of its opponents and threw the weight of his authority against the operation; though Bodez in his thesis (Paris, 1861) thought that in desperate cases a life might be saved by such means

In 1865 considerable interest in the subject was revived by Robert McDonnell, who reported a successful case of Dr. Samuel Gordon of Whitworth Hospital, Dublin. a fatal case of his own and reviewed 26 cases of trephining of the spine, in seven of which a favourable result was obtained In 1866 Jonathan Hutchinson opposed the operation in a lengthy article. in which he denied that the cord was ever permanently compressed by the bodies. by the laminæ, or by extravasated blood, but urged as his chief reason against the operation that "you convert a simple into a compound fracture and add the risks of pyæmia. together with those of spinal meningitis"

In 1869 Thomas Nunnely. in an address before the British Medical Association again brought the subject before the profession. His general conclusion

Department of Harvard University, which was founded in 1783 He served as professor of anatomy and surgery until his death in 1815

In speaking of the founding of medical schools in the United States mention should be made of that most extraordinary personality, one of the most interesting in the surgical annals of the country—namely, Nathan Smith, the exemplar par excellence of the peripatetic medical professors, in which, for a season during their early development, the medical schools of America abounded He graduated in medicine from Harvard University in 1790, and eight years thereafter, in 1798, he founded Dartmouth Medical School, where for more than a dozen years he was the entire faculty, teaching all branches and occupying what Oliver Wendell Holmes has facetiously described as "not a chair, but a whole settee of professorships" In 1813 he left Dartmouth to establish the Medical Department of Yale College in New Haven, where he filled the chair of surgery Later on he founded two other medical schools, one in Vermont, the other in Maine As this brief history would indicate, Nathan Smith was a most interesting and many-sided personality, an all-round specialist, a pioneer investigator and writer along various lines, both medical and surgical, as witness his description of typhoid fever, pronounced a classic by Sir William Osler, and his performance of ovariotomy, independently of, and a few years later than, Ephraim McDowell His studies in the pathology of necrosis of bone, the principles established by him in the use of certain apparatus for the treatment of fractures, and his studies in dislocation of the hip, all stamp him as an original thinker and a surgeon of ability Throughout a long life he was a consistent exponent of the best Hunterian traditions

Influential Helpers

It is interesting to note the very important part played by Benjamin Franklin in establishing the first medical school in the colonies It was largely due to his timely assistance and constant encouragement at a time when they were sorely needed that medical education was really begun in the States Acknowledgment should also be made of the invaluable aid and support, both material and moral, rendered these infant medical schools by the celebrated Dr John Fothergill and his successor, John Lettsom, whose interest, in the first place, was enlisted through the Society of Friends, of which both were members, and to which so large a portion of the early colonists, especially in Pennsylvania, also belonged Fothergill was the adviser of both Morgan and Bard in planning the Philadelphia and New York schools He was a generous contributor to both, and one of the incorporators of the latter He it was who, upon the founding in 1763 of the first medical library, that in connexion with the Philadelphia Hospital, presented to it the first book, a volume on Materia Medica

Up to this time the majority of American medical students had gone to Edinburgh for their medical degrees, attracted thither by the fame of the great teachers comprising the faculty at that time—Cullen, the Munros, with Black, Whytte, Bell, and others The most of these students also spent some time in London, largely attracted by the fame of Pott, Baillie, the Hunters and their school, and others It is very difficult to estimate, with any degree of exactness, the relative influence of these two centres upon the thought and practice of the American students Both influences were very potent no doubt upon the receptive minds of the eager young colonists Certain it is that, in reading the letters written by many of them while enjoying the advantages that these great centres offered, one is struck by the enthusiasm and devotion inspired by their teachers

(*To be concluded*)

GEORGIUS BUCHANANUS SCOTUS

THE human boy has a feeling of unmixed satisfaction when he has the chance of observing the dethronement of some idol which has been held as a pattern before his sinful eyes by those set in authority over him The adult joy in a corresponding situation is tempered by some sad regret at the passing of what he once held as sacrosanct Something of this feeling is produced by the latest investigations of the claims of mementos of the famous George Buchanan, whose portrait in the Senate Hall, and skull in the University Library, bear testimony to the respect and admiration given to him by his fellow-countrymen Prof Karl Pearson, when he gave the fifth Henderson Trust Lecture last June, attacked the authenticity of one or both of these presentments of the great scholar in the temple of his fame His lecture[1] deals with the known portraits, and shows us that the long, dour, and rather fanatical face of the Scottish ideal is less likely to represent the actual man, as he was, than the more human face of the Royal Society portrait The difference appears to be that between Cato and Catullus as Prof Pearson expresses it, and we seem forced to admit that the Edinburgh portrait is rather what he ought to have been—to be in keeping with the halo—than what it is possible he may really have been in his moments of relaxation According to Prof Pearson's well ordered argument, either the skull or the Edinburgh portrait is not that of the famous George Buchanan This interesting exposition of the application of anthropological artistic criticism deserves study

NEW PREPARATIONS

Messrs Burroughs Wellcome and Co state that they now supply their brand of insulin in the strength of 200 units in 5 c cm as well as in the regular strength of 100 units in 5 c cm To avoid the possibility of overdosage the more concentrated preparation is issued with a label and in a carton of distinctive colour

The British Drug Houses, Ltd , announce that they are in a position to supply to any medical men who wish to make a clinical trial of activated ergosterol a solution of 0 1 per cent of crystalline ergosterol which has been activated by irradiation under carefully controlled conditions In THE LANCET of Feb 5th, 1927, Rosenheim and Webster, discussing the nature of the parent substance of vitamin D, showed that when ergosterol is subjected to ultra-violet irradiation photochemical action results in the formation of a substance which has extraordinarily potent antirachitic properties, and that probably less than one-thousandth of a milligramme of it per diem suffices to cure rickets in a rat The manufacturers state that so far as can be foretold, this solution may be expected to possess 20–50 times the antirachitic activity of cod liver oil, thus, from ¼ to 1 c cm should prove an effective daily dose A bottle of this solution will be sent without charge to any registered medical practitioner who may apply for it

THE PAINLESS DESTRUCTION OF ANIMALS

THE manageress of Our Dumb Friends' League Home for Cats and Dogs at Bedford was convicted last week of causing unnecessary suffering to a cat which had been sent by its owner for painless destruction The Royal Society for the Prevention of Cruelty to Animals undertook the prosecution The lady to whom the cat had belonged gave evidence to the effect that about a week after she had sent the animal to the home to be destroyed in the lethal chamber it reappeared in her garden, about one and a half miles away, in an extremely weak condition and died before she could carry it indoors The defendant stated that when she took the cat out of the lethal chamber it appeared to be dead In cross-examination she said she did not notice the time at which the cat went into and came out of the box It was urged on her behalf that it was a case of error of judgment rather than an act of deliberate cruelty The magistrates fined the defendant £3 with £4 7*s* costs, the chairman remarking that there was a lack of various precautions which would have prevented the terrible suffering which the cat underwent He added that the arrangements for the destruction of animals at this home needed more careful regulation

If such incidents are repeated public opinion is likely to insist upon the registration, licensing, and inspection of institutions—other than those under the charge of a veterinary surgeon—which undertake the painless destruction of animals

"CIRCULARS"

To the Editor of THE LANCET

SIR,—In common, I suppose, with others in general practice, I frequently receive in the form of pamphlets reprints of articles by specialists When these are from authors with whom I have had professional dealings I am always glad to receive and read them, or when they are evidently distributed, not by the author himself but by some impersonal body, such as a learned society or more often, by an association founded for the promotion of public welfare, these, too, are acceptable enough

But I wish to protest against the growing habit, favoured by a certain type of specialists, of disseminating broadcast reprints of their articles to general practitioners with whom they have had no previous relations In these circumstances such pamphlets appear to be attempts at auto-advertisement, indistinguishable from the methods of the tradesman touting for orders

The general practitioner would be wise to treat them as "circulars," merely noting the names of the authors so that their services may be eschewed in the future If the General Medical Council desires to investigate this form of professional advertising, and requires material for that purpose, the contents of my waste-paper basket are always at their disposal

I am, Sir, yours faithfully,
C WILLETT CUNNINGTON

Dollis Avenue, Church End, Finchley, N , Jan 30th, 1927

Tumours of the Spinal Cord

Turning now to the more interesting subject of tumours of the spinal cord, we find that in the 50 cases collected by Horsley in 1887 and a second 50 collected later by Mills and Lloyd, the two including all those of which we have any satisfactory knowledge, no mention is made of operation in a single instance And yet as early as 1873, Leyden of Strassburg had suggested that tumours of the spinal cord might be submitted to the operation of trephining the spine as the only means of extirpating them He said that such an operation was as feasible as that for fracture of the spine, and that, in spite of the difficulties of diagnosis and the dangers of the operation, in view of their otherwise absolute hopelessness, an operation in suitable cases was wholly justifiable "Bei der volligen Hoffnungslosigkeit aber wäre ein Versuch im geeigneten Falle wohl gerechtfertigt" In one case in which he had localised the tumour, he had actually raised the question of operation, but was deterred from going further because the size of the tumour would have necessitated the removal of two vertebral arches, and the opening of the dura would have risked the setting up of a diffuse meningitis (Fig 1)

Then Erb in 1878 discussed the subject theoretically, while Byron Bramwell in 1882 urged an operation in suitable cases, and was supported by Gowers in 1886, who maintained that the removal of a tumour from the spinal meninges was a less dangerous procedure than the removal of a tumour from the brain The proof of this statement was to come in the following year through the neurological acumen of Gowers and the surgical skill of Horsley, when a previously unrecognised tumour of three years' duration lying on the left side of the fourth dorsal segment was diagnosed by Gowers on June 5th, 1887, and removed by Horsley four days later There were also present on this epoch-making occasion, which proved to be the birth of spinal tumour surgery, Dr Percy Kidd, a relative of the patient, Mr Walter Edmunds, at that time resident medical officer of St Thomas's Home, Mr Edwin Francis White, who gave the anæsthetic, the late Dr Frederick Osmund Stedman, at that time house physician at the National Hospital; and Sir Charles Ballance, who assisted at the operation (Fig 2)

Tumour removed by Horsley on June 5th 1887 (Actual size)

SPINAL PUNCTURE

Although lumbar puncture was *first* used by Corning as far back as 1885, it did not come into general use until 1891, when Quincke in Germany, and Essex Wynter in this country, brought it to the notice of the profession as a means of reducing the increased intracranial pressure in hydrocephalus Marie, Foix, and Robert in 1913 introduced double spinal puncture and showed that qualitative differences were present in the cerebro-spinal fluid above and below a spinal tumour Queckenstedt in 1916, using lumbar puncture alone, showed that the pressure in the lumbar canal rose on compression of the jugular veins when there was no spinal block, but did not do so in the presence of an obstruction This obstruction must, however, be complete, otherwise a positive result may be obtained even in the presence of a tumour

CISTERNAL PUNCTURE

Cisternal puncture was first introduced as a clinical aid in *diagnosis by Wegeforth*, Ayer, and Essick in 1919 It had long been practised on the lower animals as the easiest method of obtaining cerebro-spinal fluid These authors perfected a safe technique in man, and recommended cisternal puncture for reaching the subarachnoid space (1) when the spinal *subarachnoid* space is *blocked* by tumour, adhesions, or bony deformity; (2) in combination with lumbar puncture as a means of irrigating and draining the spinal subarachnoid space, (3) as the best method of administering remedies in meningitis

Ayer has since elaborated a method of combined cisternal and lumbar puncture as a means of determining the presence or *absence of spinal subarachnoid* block, especially in tumours The method is based upon the facts that in the normal individual the cisternal and lumbar fluids are practically identical; their pressures are the same, and oscillations due to coughing, sneezing, holding the breath, or to compression on the jugular veins (Queckenstedt phenomenon) are of similar range

Although diminished pressure below the block is usual, normal pressures are not uncommon, and occasionally an increased pressure may be found. This last may be due to a valvular action of the tumour, extramedullary in position, allowing a downward but preventing an upward flow of the fluid Exudation of serum from the distended spinal veins may also be a contributory factor.

In arriving at a diagnosis of spinal subarachnoid block, Ayer bases his judgment on the two-fold criteria —

1 Evidence of mechanical obstruction to the free passage of fluid in the spinal subarachnoid space as indicated by (*a*) pressure relations at the two points, especially changes in pressure which result after withdrawal of fluid; (*b*) variations in the normal oscillatory movements of the fluid, dependent upon the cerebral pulse and respiration, (*c*) gross changes in fluid pressure caused by pressure on the jugular veins and by coughing, all indicative of mechanical interference with the continuity of the spinal fluid column

2 Evidence of a different chemical composition of the two fluids (cisternal and lumbar) This latter is based upon the fact that the protein-content of the fluid is normally the same throughout the spinal subarachnoid space, but has *always been found increased below an obstruction.*

Ayer goes so far as to say —

> "*It is reasonable to conclude* that protein increase is a more delicate indication of cord compression or meningeal involvement than is demonstrable block"

Greenfield also, from his very large experience at the National Hospital, has expressed the same opinion as to the greater importance of the protein increase over other tests for spinal block

Normally the total amount of protein in the cerebro-spinal fluid is approximately 25 mg. *per* 100 c cm of fluid In cases of spinal block this figure may be increased a hundredfold in the stagnant fluid below the block In *addition there* also accumulates an excess of other substances, such as mineral salts and glucose, while the engorgement of the spinal vessels leading to a state of increased meningeal permeability causes the spinal fluid *to* gradually approximate in chemical composition to the blood plasma Consequently we find in the fluid elements derived from the blood stream which are normally absent Altered blood, for example, producing the characteristic yellow coloration known as xanthochromia, whilst the presence of fibrinogen may cause the fluid to clot spontaneously in the test-tube Certain antibodies, such as hæmolysin, may also be detected

The outstanding features in the cerebro-spinal fluid below an area of spinal compression are therefore (1) xanthochromia, (2) increase in the amount of protein, and (3) occasional spontaneous coagulation These *three* conditions are sometimes spoken of collectively as the "loculation syndrome" The expression "Froin's syndrome" *is sometimes* applied, but incorrectly, for Froin substituted for an increase in the amount of protein an increase in the number of cells We now know, however, *that such* a pleocytosis is an unessential and indeed an uncommon finding

Occasionally a condition *of spinal* fluid stagnation is encountered in the fluid lying immediately *above* a tumour, as shown by increased protein-content, with or without *xanthochromia* This is explained by a transudation into the fluid either from engorged was favourable to the operation This, in the same year, was refuted by Le Gros Clark, who "with every disposition to regard the subject impartially," could not regard "trephining the spine as brought within the pale of the justifiable operations in surgery."

It was at this date that a complete change of opinion appeared for the first time in that great English classic, Erichsen's "Art and Science of Surgery" In the first edition, published in 1853, appeared —

> "This operation (trephining the spine), though performed by Cline, Cooper, and Bell is, I believe, now generally abandoned by the best surgeons in this country, owing to its invariable, and, indeed, intrinsically fatal character"

And so through the next three editions But in the fifth edition, published in 1869, Erichsen comes out as a supporter of the operation in the following words —

> "The results of this operation are not very encouraging But, though so far the result has been but little satisfactory, ought surgeons to discard the operation? I think not, and we are the more justified in this course, as the operation is not necessarily dangerous to life, does not appear often to have hastened the patient's death, and has certainly, in some cases, afforded relief of the most marked character"

In 1870 Brown-Séquard, from the point of view of a neurologist and experimental physiologist, expressed the following conclusions —

> 1 That the laying bare of the spinal cord is not a dangerous operation 2 That death, after a fracture of the spine, is usually due to the effects of pressure, or of excitation of the spinal cord, and is not the result of a partial or a complete section of this organ 3 That reunion may take place after a wound of the spinal cord, so that its lost functions may return 4 That the removal of some parts of the vertebræ may be followed by a production of new bone 5 That the cases of fracture of the spine in which the trephine has been applied show the usefulness of this operation

In spite of this authoritative pronouncement, progress was slow and only isolated cases, mostly fatal, were reported by Cheever (1870), by Willard (1871), by Lucke (1880), by Stemen (1883), by Halsted (1884), and by Pinkerton (1884) The operation was variously described under such extravagant terms as "formidable," "appalling," "well-nigh impossible," "desperate and blind," "unjustifiable," "bloody and dangerous" How great the prejudice against this operation must have been, even in fairly recent times, may be judged by the article in Heath's "Dictionary of Surgery" written by none other than Herbert Page in 1881

> "The operation of trephining the spine, proposed many years ago and adopted several times, has made no progress in surgery, nor is it likely to do so It is an operation not within the range of practical surgery"

Continued Progress

Notwithstanding such uncompromising condemnation in this country, progress elsewhere continued Maydle, of Vienna, in 1882, and Morris, of New York, in 1885 made unsuccessful attempts to unite the severed ends of the spinal cord, while Abbe, in 1889, acting upon Dana's suggestion tried to unite the nerve roots above and below the level of the injury to the cord, hoping thus "to furnish a means of communication between the severed sections" The attempt proved too difficult of accomplishment and had to be abandoned John Duncan, in Edinburgh in 1889, tried to obtain union of the severed cord by simply drawing the ends of the torn dura together and stitching them there, in order to relax tension on the cord But no improvement followed

In February, 1885, William Macewen, operated upon a man, who had a complete paraplegia with bed-sores, resulting from an injury to his lower dorsal spine eight weeks previously The arch of the twelfth dorsal vertebra was found fractured and depressed It was removed together with "a connective tissue tumour" lying between it and the theca, A year later the patient could walk with ease and without support

While Werner was able to find only six cases that had survived the operation out of 31 operations of trephining the spine, it must be remembered that all belong to the pre-Listerian era of surgery Immediately following upon the introduction of antiseptics, greatly improved results were forthcoming, and of 13 operations for fracture of Macewen, Morris, Horsley, Lauenstein, Lucke, Albert, Duncan, Pean, and Allingham, there were three complete recoveries, two recoveries with benefit, seven recoveries unimproved, and one death

Pott's Disease

It followed naturally that attention should begin now to be directed to cases of paraplegia due to Pott's disease Hippocrates had already observed that the palsy of the legs and arms, the wasting of the body, and the retention of urine happen chiefly in those cases where there is no spinal deformity, nor any projecting bone forward or backward, and paralytic affections take place the least frequently in cases of gibbous or angular projections And Percival Pott writing in 1720 on the "Useless State of the Lower Limbs in Consequence of a Curvature of the Spine" says —

> "Since I had been particularly attentive to the disorder, I thought that I had observed that neither the extent nor degree of the curve had in general produced any material difference in the symptoms, but that the smallest was, when perfectly formed, attended with the same consequences as the largest, and that the useless state of the limbs is by no means a consequence of the altered figure of the spine, or of the disposition of the bones with regard to each other, but merely of the caries"

Michaud in 1871 fully elucidated the mechanism of paraplegia in Pott's disease, while Thomas Buzzard in 1880 showed that, even in cases with abrupt angular deformity, the compression did not depend upon the distortion of the vertebral canal, but upon inflammatory products lying outside the dura

On May 9th, 1883, Macewen in a case of angular curvature of the spine with complete sensory and motor paraplegia, with incontinence of urine and fæces, and of two years' duration, removed the laminæ of the fifth, sixth, and seventh dorsal vertebræ Between the theca and the bone he found a fibrous neoplasm one-eighth of an inch in thickness, firmly attached to about two-thirds of the circumference of the membrane This was carefully dissected off, with the result that improvement began in 24 hours, going on to complete recovery, so that five years after the patient was playing football and other games This case was followed by four others of a similar nature, two of which were successful and two fatal, one a week after operation and the other eight months later from generalised tuberculosis Macewen's success was speedily followed by others, Horsley, White, Abbe, Duncan, Lane Podres, Boeckel and Israel, reporting successful cases, all of which went to show that in the majority of cases the paraplegia is due to an external pachymeningitis with the formation of an extra-dural connective tissue tumour

aspects of the canal probably held up at the exit of the posterior roots or at the attachments of the ligamentum denticulatum (Fig 4) Radiograms are taken at once after the injection with the patient's head and shoulders raised after cisternal injection and with the patient in the Trendelenburg position after lumbar injection. Should there be a block after cisternal injection additional radiograms should be taken at the end of six hours again in 24 hours and at the end of a week In this way any alteration of the level at which the lipiodol was first checked may be determined

Irritation of Meninges by Lipiodol.

Can the claim that lipiodol is completely non-irritating to the meninges and can be injected with unlimited tolerance be maintained?

Ayer and Mixter found that in animals there was a meningeal reaction which reached its height in from 24 to 48 hours when counts of 1000 cells with moderate increase in the protein-content of the cerebro-spinal fluid were noticed. This reaction subsided gradually, and by the tenth day the fluid was normal I have noticed a distinct meningeal reaction in patients submitted to operation shortly after the injection of lipiodol. The meninges appeared thickened somewhat reddened and agglutinated, while the cerebro-spinal fluid was slightly turbid. Mixter reports a similar condition as does de Martel who however, does not mention the cerebro-spinal fluid Sharpe and Peterson report a case where such an inflammatory reaction occurred from the arrested lipiodol at the site of the spinal block in the mid-dorsal region that the patient's symptoms and signs were aggravated to a degree necessitating its removal five and a half months after by laminectomy The lipiodol was found as two encysted globules surrounded by numerous newly formed adhesions In all their other cases the clinical signs and symptoms were aggravated by the lipiodol injection veins in the spinal canal or from the tumour itself. As the syndrome occurs in conditions other than tumour, the former would appear to be the more acceptable theory.

In passing, I may mention that the upper limit of the sensory loss may be raised higher than that due to the tumour itself by the pressure of this stagnant column of cerebro-spinal fluid, causing a localised ischæmia of the cord

PNEUMOMYELOGRAPHY.

The gradual substitution of the cerebro-spinal fluid in the lateral ventricles by air, followed by an X ray of the head as an aid to the diagnosis and localisation of brain tumour, was first introduced by Dandy of Baltimore, who claims to have increased the percentages of correct diagnosis by 10–35 per cent over those obtained by purely clinical methods This method of direct insufflation of the ventricles with air was followed by the endolumbar method, devised independently by Dandy, Bingel, and Wideroe, which consists of a replacement of the cerebro-spinal fluid by air by means of lumbar puncture

With the patient recumbent but at an angle of 50 to 60 degrees, to allow the air to rise quickly in the sub-arachnoid space 10 c cm of cerebro-spinal fluid are withdrawn by lumbar puncture and an equal amount of air injected In the absence of any spinal block the air passes at once into the cranial subarachnoid space As a result the patient complains immediately of "a fairly sharp pain" first in the posterior, then in the middle, and finally in the anterior part of the side of the head which is uppermost According to Dandy, so constant and characteristic is this pain that it can be taken as positive evidence of the absence of a complete spinal block In the presence of such a block no such pain is complained of Other observers report, in addition to the severe headache, nausea and vomiting, a rise in temperature, and at times collapse, as sequelæ to the endolumbar method If on injection air reaches the head at once no more than 10 c cm is used If, however, it does not pass up into the cranial cavity, Dandy advises the injection of as much air as the spinal canal will hold, in order to obtain the maximum effect of the air shadow for the X ray localisation of the tumour

Apparently air in the spinal subarachnoid space produces no pain comparable to that in the cerebral subarachnoid space, though root pains, unilateral or bilateral, due to the irritation of the air, will radiate along the course of the nerves fixed by a tumour In Dandy's experience, these pains have always localised a tumour when present Fleeting and less constant pains may be experienced also in the absence of spinal block

Liberson in America has devised what he calls "a simultaneous displacement apparatus" for use in the endolumbar method, in support of which he claims that "clinical methods without roentgeno-graphic aid are insufficient for localisation of early brain and cord lesions" As I gather that he is more interested in the roentgenographic than in the neurological aspect of the subject he can scarcely be regarded as an unbiased witness

A very striking commentary upon this method comes from Wideroe, one of its originators He reports 11 cases of spinal block, in none of which was he able to discern any shadow whatever by X rays following endolumbar air replacement, and Eskuken says that, owing to the difficulty of observing anything distinctly, the procedure is often useless

LIPIODOL

Various attempts had been made by Krause, Simons, and others to visualise the spinal theca by means of solutions opaque to the X rays, but without success Sicard and Forestier of Paris succeeded in solving the problem by using an iodised oil called "lipiodol" for cisternal and lumbar puncture Lipiodol, a preparation of poppy-seed oil in which iodine has been incorporated, was originated by La Fay in 1921 and used by him in the treatment of epidemic encephalitis As this substance did not appear especially irritating to the meninges and was opaque to the X rays, Sicard and Forestier tried it with a view to localising spinal cord compression and were successful

There seems to be no marked difference between the French preparation, lipiodol, and its German relative iodipin, as far as radiopacity and physiological effects are concerned The iodine-content is the same in both—i e , 40 per cent. by weight, or 0 45 g per c cm The iodine is not simply in solution but in the form of a fairly stable chemical combination Lipiodol is a transparent oil of an amber yellow colour and high specific gravity (1350) Its radiopacity is due to the high atomic weight (127) of its iodine component, while its heavy density explains its passage by gravity from the cisterna magna to the lumbar cul-de-sac

A more recent modification of lipiodol is the so-called "lipiodol ascendant" or "lipiodol montant" It is lighter than the cerebro-spinal fluid and ascends in the spinal canal when injected into it in the lumbar region The diminution of its iodine-content, however, reduces its value as a radiopaque medium Moreover, it has a tendency to adhere to the meninges in its upward passage, causing difficulty or confusion in the interpretation of the X ray shadows For these reasons we have not found it satisfactory at the National Hospital Peiper has rejected it entirely on similar grounds

Technique

Lipiodol may be injected either into the cisterna magna or into the lumbar canal if the lower level of a block is to be localised No cerebro-spinal fluid should have been removed from the patient for several hours previous to the injection

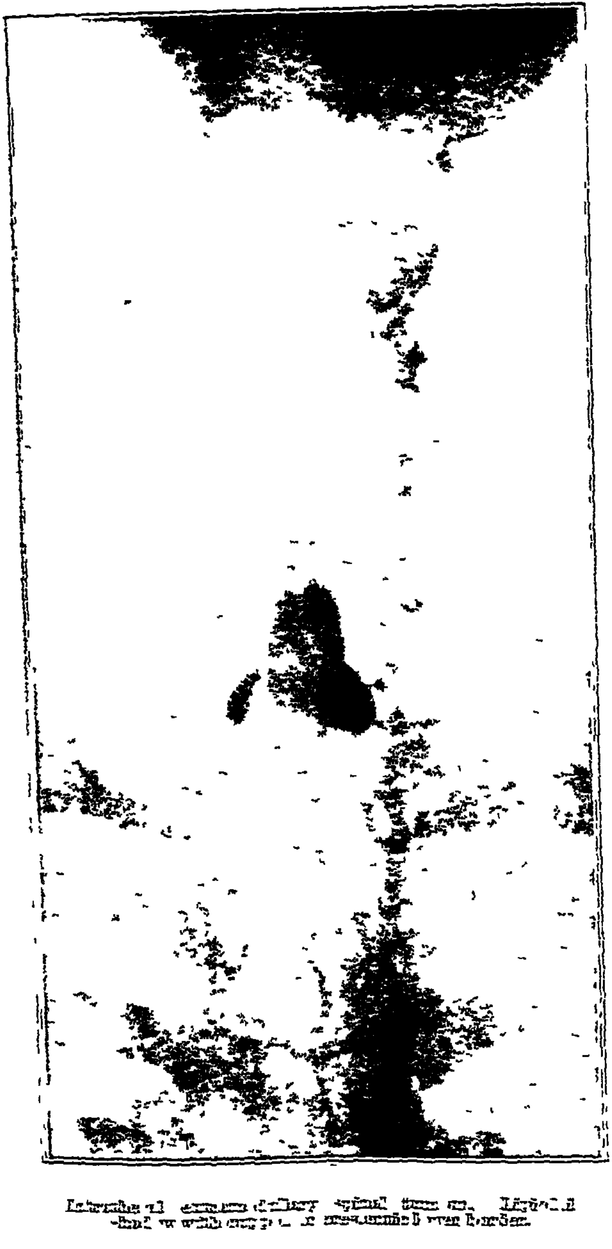
If the injection is into the cisterna magna, it is best and most conveniently done with the patient sitting up in a chair, with the head strongly flexed upon the chest, to open up the space between the occipital bone and the atlas After preparation of the skin, a point, just to one or other side of the ligamentum nuchæ, is taken on a line joining the tips of the mastoid processes If thought necessary, the place of puncture may be anæsthetised with a 2 per cent solution of novocaine It is well to give the patient a hypodermic injection of morphia, gr ¼, an hour previous to the injection. It conduces to a quiet mind in the unusual surroundings of the X ray room and alleviates some of the sequelæ to be described later A spinal puncture needle is entered at the spot selected and pushed steadily forward with a slight inclination upwards in a line with the external auditory meatus and the glabella Should the point come in contact with the occipital bone, the needle is depressed slightly and pushed slowly but steadily through the atlanto-occipital ligament and dura The cessation of all resistance at once indicates that this has occurred Sicard suggests that normal saline solution should be slowly injected as the needle is introduced, to keep the lumen patent, to indicate by the sudden decrease of resistance that the puncture is accomplished, and to remove the medulla from any injury from the entering needle point No cerebro-spinal fluid escapes as a rule, and requires to be withdrawn by a syringe But only a very few drops for the purpose of verification should be withdrawn or allowed to escape Then 1 to 1 5 c cm of the lipiodol is injected slowly, followed by a little warm saline to wash out any lipiodol remaining in the needle The needle is then withdrawn.

One or two points may be emphasised (1) The oil must be clear and transparent Brown or turbid oil has deteriorated and should not be used (2) The viscosity of the oil may be decreased by placing the ampoules in warm sterile water, thus facilitating its injection (3) Care should be taken to see that the syringe is free from air bubbles before the injection. They tend to hold up the lipiodol at the sides of the meninges

The technique for lumbar injection is essentially the same but is best performed with the head and shoulders low and the buttocks well raised

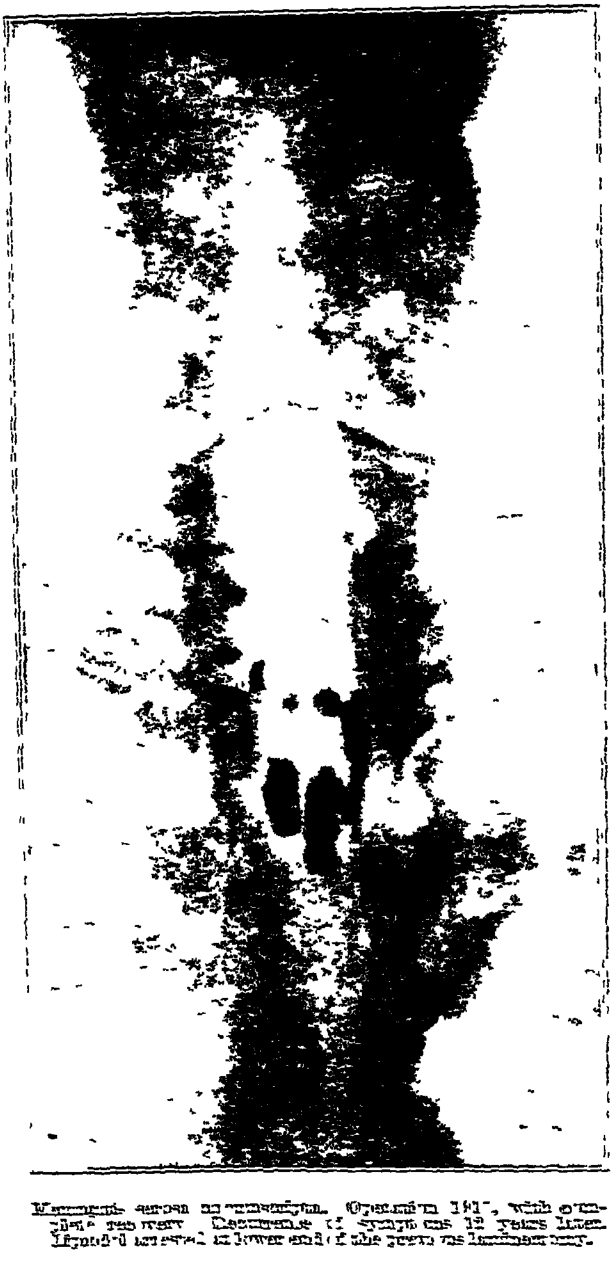
After cisternal injection, and in the absence of any block, the lipiodol reaches the dural cul-de-sac at the level of the second sacral vertebra in a very short time (5–6 minutes) It forms here a large, round, oval or irregular globule Occasionally there may be some delay at the level of the fourth dorsal vertebra, the narrowest part of the canal Frequently small particles of the lipiodol are seen on the lateral

FIG. 3.



Intradural extramedullary spinal tumour. Lipiodol shadow with cupped or crescentic lower border.

FIG. 4.



Meningitis serosa circumscripta. Operation 1915, with complete recovery. Recurrence of symptoms 12 years later. Lipiodol arrested at lower end of the previous laminectomy.

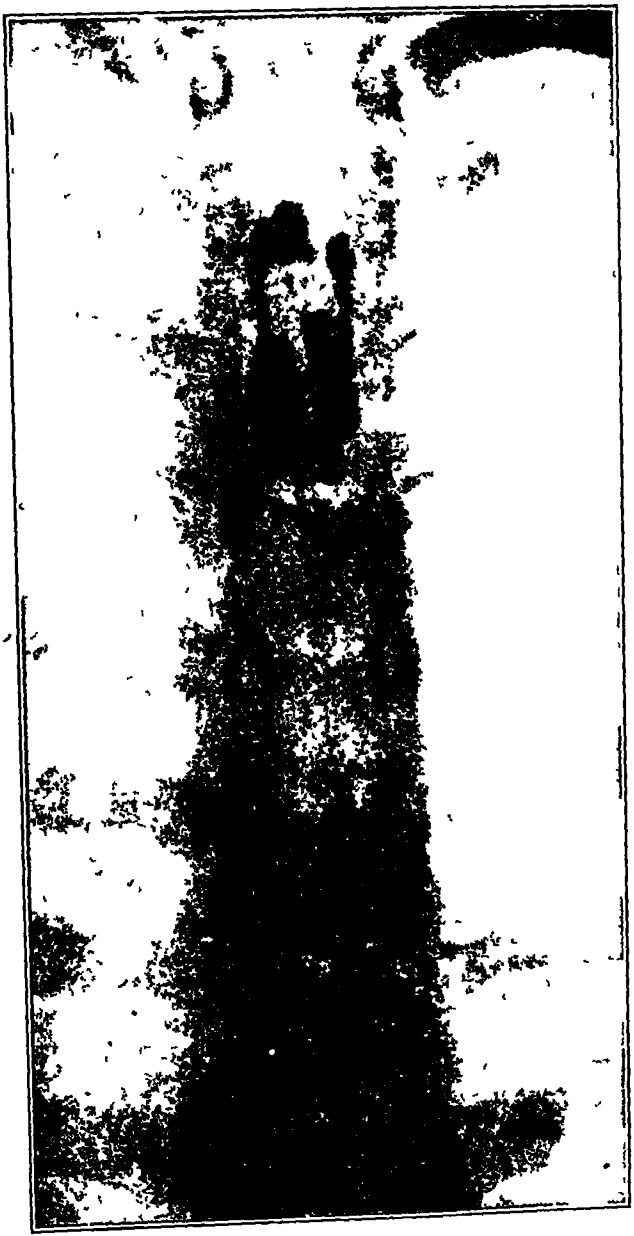
aspects of the canal, probably held up at the exit of the posterior roots or at the attachments of the ligamentum denticulatum. (Fig. 4.) Radiograms are taken at once after the injection, with the patient's head and shoulders raised after cisternal injection and with the patient in the Trendelenburg position after lumbar injection. Should there be a block after cisternal injection additional radiograms should be taken at the end of six hours, again in 24 hours, and at the end of a week. In this way any alteration of the level at which the lipiodol was first checked may be determined.

Tolerance of Meninges to Lipiodol.

Can the claim that lipiodol is completely non-irritating to the meninges and can be injected with unlimited tolerance be maintained?

Ayer and Mixter found that in animals there was a meningeal reaction which reached its height in from 24 to 48 hours, when amounts of 1·0 c.cm. with moderate increase in the protein-content of the cerebro-spinal fluid were noticed. This reaction subsided gradually, and by the tenth day the fluid was normal. I have noticed a distinct meningeal reaction in patients submitted to operation shortly after the injection of lipiodol. The meninges appeared thickened, somewhat reddened and agglutinated, while the cerebro-spinal fluid was slightly turbid. Mixter reports a similar condition, as does de Martel, who, however, does not mention the cerebro-spinal fluid. Sharpe and Peterson report a case where such an inflammatory reaction occurred from the arrested lipiodol at the site of the spinal block in the mid-dorsal region that the patient's symptoms and signs were aggravated to a degree necessitating its removal five and a half months after by laminectomy. The lipiodol was found encapsulated in cysts, surrounded by masses of newly formed adhesions. In all the other cases the clinical signs and symptoms were aggravated by the lipiodol injection.

FIG. 5



Intrathecal extramedullary spinal tumour Lipiodol shadow with small cupped or crescentic lower border

FIG 6

Extrathecal spinal tumour with sensory lipiodol dissociation Sensory level at the fourth dorsal segment Lipiodol arrested between the fifth and sixth dorsal vertebræ The tumour lay beneath the lower part of the lamina of the sixth dosal vertebra

Moniz of Lisbon reports these sequelæ following upon lipiodol injection in a case of hypertrophic meningitis associated with cavity formation in the cord

"The next day the patient complained of a sense of constriction in the upper part of the chest and diminished power in the upper limbs He could not flex nor extend the fingers, lost the power of flexion of the forearms and movements of the arms and shoulders He had for several days movements which resembled myoclonic contractions in the arms and forearms Examination revealed that a very slight hypoæsthesia reached to the middle of the neck These symptoms passed off in three weeks"

Moniz attributes them to a local irritation caused by the lipiodol and thinks they are determined by the local state of the meninges and cord He has also seen similar, but less intense, phenomena in cases of meningitis serosa circumscripta He thinks such sensori-motor disturbances following the injection of lipiodol point to a diagnosis of pachymeningitis

At the National Hospital, following upon the injection of lipiodol, there has been found commonly (1) Increase in the root-pains at the site of the lesion, lasting for some hours (2) General soreness and stiffness of the back muscles (3) Headache (4) Rise in temperature Less commonly, there has been increased difficulty in micturition in cauda equina lesions In a case which eventually proved to be one of disseminated sclerosis, injection of lipiodol gave rise to pain on one side of the face, twitching of the left arm and leg, with sensation of pins-and-needles in the left leg These symptoms lasted for 24 hours

Ebaugh and Mella, who have investigated the subject, find that pains in the legs occurred in 30 per cent of patients, rise in temperature (101 6°) in 23 per cent, nausea and headache in 7 per cent, leucocytosis in 30 per cent, pleocytosis in 60 per cent, and sleeplessness and restlessness were "frequent" From the cellular increase in the cerebro-spinal fluid the increase in the protein-content, and the frequent presence of blood on lumbar puncture (27 per cent) they conclude that as a result of the lipiodol injection an aseptic chemical meningitis is produced These local and systemic symptoms usually disappear after a few days without apparently any permanent effects

Forestier maintains that any severe sequelæ are not due to the lipiodol but to the puncture alone He does not think that the lipiodol should be regarded as a permanent foreign body, because even if it takes a long time to be absorbed the absorption is at any rate continuous by means of a normal histological reaction

Interpretation of the Results Obtained.

How much reliance can be placed upon lipiodol localisation? A correct interpretation of the X ray films is of paramount importance. The lipiodol may move slowly, or even be held up for a short time, the false arrest ' of French writers Such temporary arrest may take place, as before mentioned, at or about the level of the fourth dorsal vertebra, and in small rounded masses at irregular intervals on the walls of the spinal canal. These latter are of little or no significance. Laplane thinks that ' false arrest " can be differentiated from true arrest by the shape of the shadow and by its fixation In the latter the lipiodol has stopped owing to a real obstruction, and reversal of the patient s position will cause it to flow away again In false arrest on the contrary, the lipiodol has become adherent to the meninges or nerve roots, and will not alter its position on reversal of the patient.

It would be of great importance if the shape of the lipiodol shadow could give any indication as to the nature of the lesion or process involved. Mixter thinks that it can and says that a cap or crescent, complete or incomplete, means an extramedullary tumour, or Pott s disease with an intraspinal abscess: while narrow lines of lipiodol at either side with an irregular mass above suggest a fusiform enlargement of the cord itself. (Figs. 3 and 5) But the consensus of opinion does not support him. Eskuchen in Germany and Piccinnino in Italy hold that it has not proved possible, as was at first hoped, to draw any conclusion from the form of the lipiodol shadow as to the nature of the process involved

On this point the findings of Mme. Sorell-Dejerine, with reference to paraplegia in Pott s disease are most interesting and instructive. In cases in which the paraplegia had been transitory, probably from œdema or vascular disturbances the transit of the lipiodol was normal In cases cured of the paraplegia, which had been associated in its development with an intravertebral abscess, there persisted a slight hold-up at the level of the original lesion but this was only transitory and after a few days all the lipiodol was found in the dural cul-de-sac. In a developing paraplegia associated with an intravertebral abscess there was a lipiodal arrest, the lower limit of which was not horizontal, but had one or several prolongations This arrest persisted as long as the paraplegia was stationary When the compression regressed the lipiodol progressively fell as the subarachnoid space became freer. In old cases of paraplegia associated with a pachymeningitis the lipiodol arrest persisted with a distinct and horizontal lower border

Moniz describes the unusual and interesting behaviour of lipiodol in a case of hypertrophic pachymeningitis with cavity formation in the cord

> The lipiodol had never become fixed during the course of three months An hour after injection it was arrested at the level of the atlas and axis, but 24 hours later it had become elongated and showed a tendency to divide into two parts The next day it had divided one part remaining in the original place the other lying between the third and fourth cervical vertebræ with a small piece at the fifth. Nine days later the detached portion had progressed in chain formation as far as the seventh cervical and upper dorsal vertebræ. Ten days later or 20 days after the injection, none of the lipiodol had reached the cul-de-sac. In the cervical region there were large scattered drops, but it lay mostly at the level of the fourth and fifth dorsal vertebræ, with some also in the lower dorsal region.
>
> Three months afterwards, scattered droplets of varying size were found in the cervical region and in smaller numbers at the level of the first and second dorsal vertebræ The lipiodol which had descended started from the fifth dorsal, but was more compact at the level of the tenth, eleventh, and twelfth dorsal where it had taken the form of a stalk occupying the mid-region with slight interruptions in its length.

Negative Findings

Babinski and Vincent have raised the question of the value of negative findings with lipiodol Can medullary compression be excluded with a negative lipiodol result? Assuredly not Ayer holds that fluid findings by his combined method may be normal in every respect even in the presence of compression of the cord. He quotes in support of his thesis a case in which a multilocular epidural cyst was found at subsequent operation Carmichael has recently seen in London a spinal tumour at the level of the ninth dorsal segment removed from a patient in whom the lipiodol findings were absolutely negative. Wilfred Trotter informs me that he has operated on cases in such an early stage that the lipiodol transit must have been uninterrupted In 1925 I operated on a patient of Gordon Holmes who had localised a tumour three months after the onset of root-pain. Here the very small size of the tumour could not possibly have interfered with the descent of the lipiodol. There is no doubt that with small tumours, or in rare cases where narrowing of the cord results from destructive new growths such negative results will occur Yet, like other French enthusiasts, Forestier says that the great diagnostic value of lipiodol is that it reveals spinal compression long before sensory changes or paraplegia appear.

De Martel reports four cases with arrest of lipiodol at a definite level for which he could find no adequate reason at the time of operation. In two of them it would appear that the lipiodol arrest was the only indication for operating.

Conflicting Evidence.

Again cases occur in which the neurological and lipiodol levels do not correspond. In other words, there is a sensory-lipiodol dissociation. In some the sensory level is higher than that of the lipiodol arrest. (Fig 6)

> Such a one occurred in the service of Grainger Stewart at the National Hospital in 1925 There was complete anæsthesia and analgesia up to the level of the fourth dorsal segment with a band of hyperesthesia. Lipiodol showed an arrest between the fifth and sixth dorsal vertebræ On removing the second third and fourth dorsal laminæ no pulsation of the cord was visible. On opening the dura, the cord presented without pulsation, enveloped in a cystic formation of milky arachnoid membrane, which appeared to be widespread The spinal veins were varicose and tortuous Above the level of the fourth dorsal segment the cord pulsated.
>
> In the belief that the condition was a circumscribed serous meningitis, the adhesions were freed as far as possible and the wound closed. No improvement followed, however, and the patient died
>
> As a result of the autopsy, Dr J G. Greenfield reported "a tumour the size of a large broad bean compressing the left posterior region of the cord but lying altogether outside the dura. It lay between the left sixth and seventh dorsal transverse processes and passed forwards slightly in the intercostal space being attached to the left sixth dorsal root. The laminectomy wound ceased at the fifth dorsal spine and transverse processes and as the tumour lay under the lower part of the lamina of the sixth dorsal vertebra, it had not been found ' Microscopically, it proved to be a neurofibroma.

And again the lipiodol may be arrested at a point two or three segments higher than the sensory level Souques noted in one of his cases an error of three segments and Moniz in one of his an error of two segments

In the one case the sensory-lipiodol dissociation may be explained on the assumption that the higher sensory level is due to the pressure of the stagnant fluid above the tumour and a localised ischæmia of the cord In the other, the lipiodol may be held up by meningeal adhesions above a tumour, or, in a case of meningitis serosa circumscripta, at a level higher than the place where actual compression of the cord begins

Given a sharp sensory level I much prefer to depend upon it alone and to operate without the use of lipiodol One has then a clean operative field within the canal, where a clear vision is of such a great preliminary advantage, and the clean and rapid removal of the tumour, or the separation of adhesions is not impeded by the dirty mess resulting from the lipiodol It is in cases, in which the sensory level is not sharp and well defined, but gradually fades away as one passes upwards, that lipiodol has its greatest field of usefulness

The Place of Myelography in Diagnosis

It is not to be wondered at that any means which can be readily and easily applied, and is thought to provide a royal road in such a difficult field as the diagnosis and accurate localisation of spinal cord compression, should have been eagerly seized upon and widely exploited This has happened with lipiodol. Yet it is surprising that from the home of labour-saving devices, America, there should arise such widespread and emphatic warnings against its indiscriminate use and abuse

Mixter, of Boston, says —

> "In the practice of medicine we must look more or less askance at any new diagnostic procedure which may carry a considerable element of danger For this reason it is wise to consider carefully the use in the cerebro spinal space of a substance opaque to the roentgen ray."

Schmidt, of Denver, has just recently summarised his views on the use of lipiodol in the following words —

> "The problem of myelography may be considered solved as far as the principles and the technique of the method are *concerned*, *it is not solved as far as the contrasting medium* is concerned Both iodized oils available at the present time, lipiodol as well as iodipin, should be used only under the strictest observation of indications and precautions"

Even Dandy, one of the originators of the endolumbar air replacement method of localisation, acknowledges that a correct diagnosis and localisation of spinal tumours can be made in over 90 per cent of cases by a "painstaking neurological examination"

I consider myself very fortunate in being attached to a hospital for nervous diseases, where the art and science of diagnosis and localisation have reached an extraordinarily high level I find that in the last five years 98 per cent of our cases of spinal tumour have been correctly localised by such painstaking neurological examination For this reason one has had to have less recourse to what I may call artificial aids to diagnosis and localisation than might have been necessary under different circumstances

In conclusion, I would formulate the following rules regarding the use of lipiodol in the diagnosis and localisation of spinal cord compression —

1 Its use should in no way usurp the place of careful and repeated systematic clinical examinations of the patient, especially with reference to a sensory level combined with laboratory tests of the cerebro-spinal fluid Recourse to it as a labour-saving device and a short cut to diagnosis and localisation cannot be too strongly deprecated

2 It should only be used after a subarachnoid block has been first demonstrated by the combined cistern-lumbar puncture method introduced by Ayer

3 It should not be used unless the possible dangers and complications are outweighed by the more exact localisation likely to be obtained

4 Finally, in properly selected cases we have in lipiodol a definite aid in the study of spinal cord compression, which, if used intelligently, will increase definitely our successful removal of spinal cord tumours at an earlier stage in the course of the disease, and thereby increase our percentage of cures and reduce our operative mortality

CARDIOSPASM.

By JOHN MORLEY, Ch M. Manch., F.R C S Eng ,
Hon consulting surgeon, Ancoats Hospital; Hon. assistant surgeon, Manchester Royal Infirmary, lecturer in applied anatomy, Manchester University

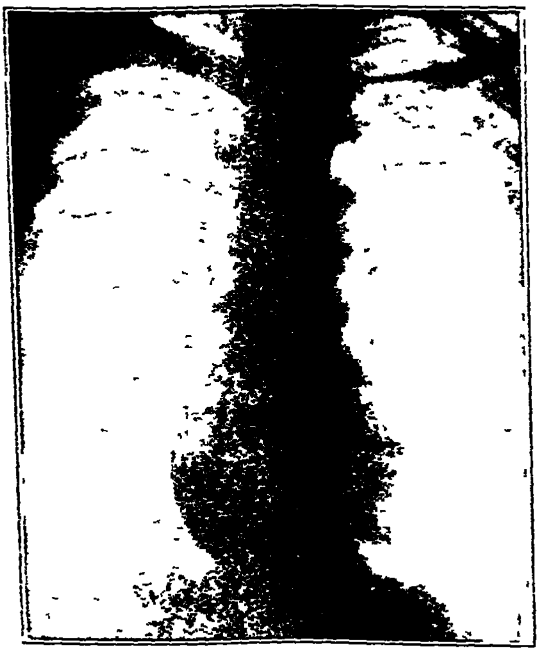
The various terms under which this remarkable condition has been described—viz , cardiospasm, achalasia of the œsophagus, idiopathic dilatation of the œsophagus, phrenospasm, hiatal œsophagismus indicate how little is known with regard to its essential nature and causation Before entering upon a brief discussion of these problems it will be convenient to describe in some detail a few illustrative cases

Clinical Records

Case 1 —A. H , a married woman aged 44, began to suffer from pain under the sternum eight years ago, at the age of 36 This pain was noticed immediately after a meal. After a few months she became conscious of difficulty in swallowing and fluids presented quite as much difficulty as solid food X ray examination at Ancoats Hospital, when the symptoms had persisted for one year, showed a great ballooning of the œsophagus, which the radiologist considered to be due to an organic stricture. There was, however, no history of swallowing a corrosive fluid, while the radiographic appearance did not suggest carcinoma. Attempts to pass bougies into the stomach proved unsuccessful, and were not persisted in for fear of penetrating the ballooned œsophagus Under a general anæsthetic I performed a gastrotomy and found that I was able to pass a full-sized bougie from the stomach up through the cardia with the greatest ease.

After this operation it was found possible to pass a large bougie into the stomach from above, and this was carried out at frequent intervals for some months For the first 12 months after operation the swallowing was much better

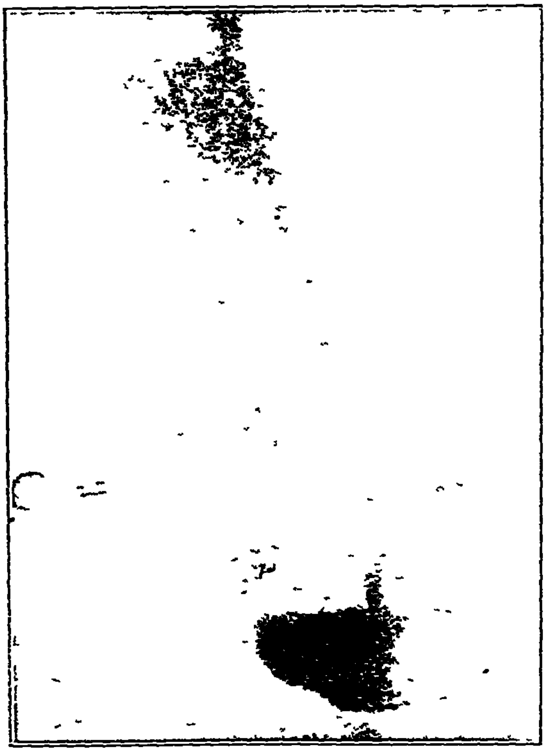
Fig. 1



Case 1 —Showing barium meal held up in lower end of œsophagus

After that period the pain and dysphagia returned, and have troubled her more or less ever since. Of late years she has obtained little relief from the passage of bougies When she feels the food obstructed there is severe retrosternal pain, which is only relieved by "vomiting" up the contents of her œsophagus She states that she brings up a large amount of slimy stuff—so much, in fact, that she does not know where it all comes from. She is thin, but for the last six years her weight has remained constant. The present state of her œsophagus is shown in Fig. 1, in which some barium porridge is seen held up on the lower end of the greatly dilated œsophagus. In Fig 2 a mercury tube has been passed into the stomach. The tube was guided through the cardia under the fluorescent screen, and its passage into the stomach excited considerable retching and nausea.

Fig. 2.



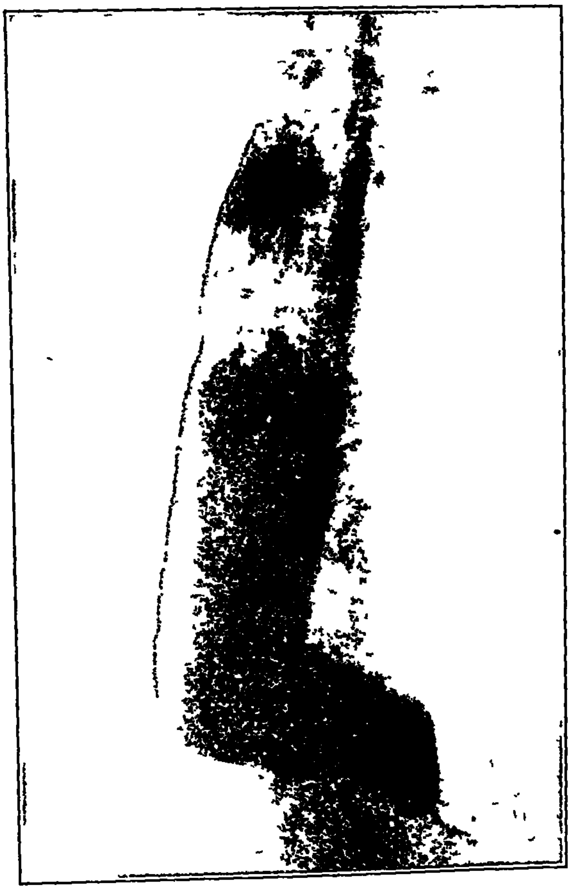
Case 1.—Showing mercury tube passed into stomach (lower shadow), with some barium still held up in lower end of dilated œsophagus

Case 2 —M. M. a married woman aged 25, was admitted to the Royal Infirmary under my care on Feb 6th, 1925, complaining of difficulty in swallowing The trouble began at the age of 14, when for no apparent reason she began to "vomit" after each meal. For a period of about two months she had to get up from the table regularly, and returned most of her food unchanged. One day, feeling that the food was lodging in her throat she found that by pressing her finger-tips deeply into the suprasternal notch, leaning forward, and making a forcible effort to swallow, she could push the food down into the stomach and obviate the ' vomiting" Since learning this trick she has never ' vomited," but at the end of a meal a mouthful or two of food will sometimes regurgitate into her mouth. She can usually succeed, by making a forcible effort in the manner described above in propelling the greater part of a meal down into the stomach. When she does so she is conscious of a sense of relief, though she complains of no actual pain while the food is held up in the œsophagus Her weight has kept fairly constant, and is now 7st 4½ lb The dysphagia never varies from day to day, unless she has a cold, when it is usually a little worse.

Previous Medical History—She suffered from "bilious attacks" with headaches when a young girl, but not since she grew up Menstruation began at 16 She married at 21 and has had three children She had no unusual amount of morning sickness in any of the pregnancies, and the dysphagia was neither better nor worse during pregnancy and puerperium. The family history revealed nothing of importance.

Condition on Admission—The patient was a small, spare young woman intelligent but decidedly not neurotic with a slight prominence of the thyroid. The prominence was found to depend on the presence of food in the dilated œsophagus, as it disappeared after washing out the œsophagus X ray examination (Fig 3) showed enormous dilatation of the œsophagus throughout its whole length Practically all the barium porridge was held up by the cardia, and the œsophagus showed increase in length as well as in width, so that it was coiled up above the diaphragm in an S shape When the patient pressed on her suprasternal notch and made a violent effort to swallow, a considerable amount of food, perhaps half the contents of the œsophagus, was forced into the stomach

FIG 3.



CASE 2 —Barium in dilated S shaped œsophagus

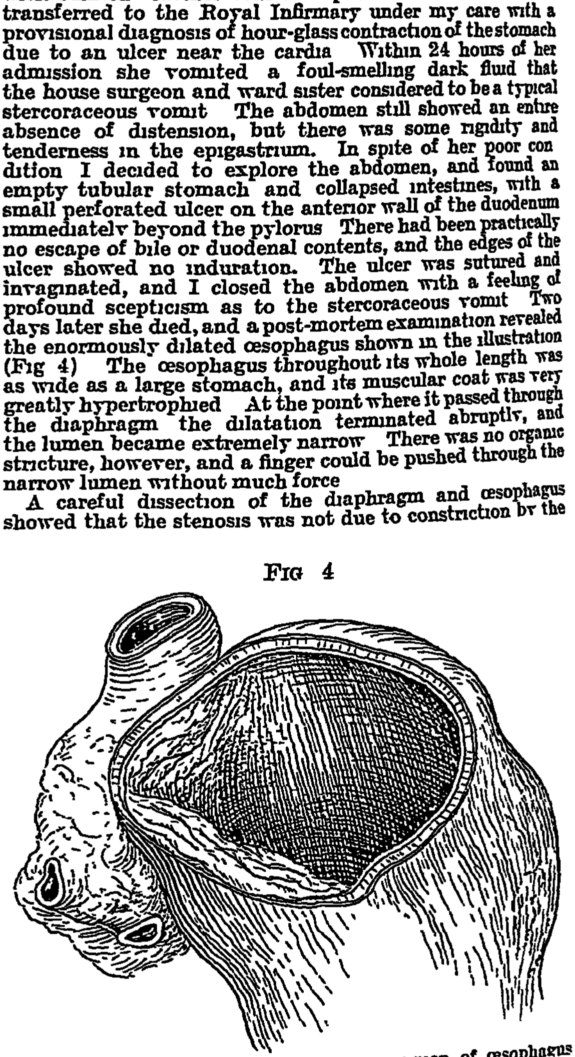
An attempt was made to guide a Hurst's mercury tube through the cardia while the patient stood upright behind the fluorescent screen The tube curled up in the ampulla of the œsophagus without engaging in the cardia, and as it caused much retching, the attempt was soon abandoned. For the next week the œsophagus was washed out daily with a stomach-tube and funnel, and the patient learned to tolerate the passage of the tube without retching At the end of a week a second attempt was made with the mercury tube Seated behind the fluorescent screen the patient herself lowered the tube down the œsophagus The first attempt was unsuccessful, and the tube was coiled up in the lower end of the gullet The tube was then withdrawn a little, and the patient was asked to lean sideways towards the left The end of the tube was seen to engage in the cardia, which, after holding it up for a short time, relaxed under its weight and allowed it to slip through into the stomach Its passage into the stomach caused a violent attack of retching and vomiting The tube was easily withdrawn The next day the patient found that she could herself pass the tube into the stomach without difficulty She is now at home, and has been given a mercury tube to use daily

CASE 3 —H E, a married woman aged 39, was admitted to St Mary's Hospital, Manchester, on Jan 22nd, for what was considered to be hyperemesis gravidarum She was six months' pregnant She gave a history of intermittent epigastric pain after food and sickness for the last 16 years She had had one full-term baby, and had suffered considerably from sickness during that pregnancy The vomiting during the present pregnancy had been persistent from the third month, and for the last month before admission had been very severe Latterly she had vomited as many as 20 times a day, and had been unable to retain even fluids

Her condition on admission was one of extreme weakness and emaciation and she vomited after every drink On the third day after admission she had a complete spontaneous abortion, but without any relief as regards the incessant vomiting I was asked to see her five days after the abortion. She was then in a desperately weak condition, emaciated, with sunken features and a scaphoid abdomen She was transferred to the Royal Infirmary under my care with a provisional diagnosis of hour-glass contraction of the stomach due to an ulcer near the cardia Within 24 hours of her admission she vomited a foul-smelling dark fluid that the house surgeon and ward sister considered to be a typical stercoraceous vomit The abdomen still showed an entire absence of distension, but there was some rigidity and tenderness in the epigastrium. In spite of her poor condition I decided to explore the abdomen, and found an empty tubular stomach and collapsed intestines, with a small perforated ulcer on the anterior wall of the duodenum immediately beyond the pylorus There had been practically no escape of bile or duodenal contents, and the edges of the ulcer showed no induration. The ulcer was sutured and invaginated, and I closed the abdomen with a feeling of profound scepticism as to the stercoraceous vomit Two days later she died, and a post-mortem examination revealed the enormously dilated œsophagus shown in the illustration (Fig 4) The œsophagus throughout its whole length was as wide as a large stomach, and its muscular coat was very greatly hypertrophied At the point where it passed through the diaphragm the dilatation terminated abruptly, and the lumen became extremely narrow There was no organic stricture, however, and a finger could be pushed through the narrow lumen without much force

A careful dissection of the diaphragm and œsophagus showed that the stenosis was not due to constriction by the interlacing fibres of the right crus of the diaphragm, but to a contraction of the circular muscle-fibres of the œsophagus The circular coat was not thicker at the point of constriction than in the hypertrophied wall above this joint

FIG 4



CASE 3 —Drawing from post-mortem specimen of œsophagus cut transversely Contrast with section of normal trachea on left

CASE 4 —F J C, male aged 36, began to suffer from dysphagia seven years ago It became so severe that he lost weight rapidly, and when he first consulted me six months after the onset he was nearly 2 st below his normal weight of 11 st After his meals, especially if he bolted his food, he would feel a choking sensation, and would have to return the meal X ray examination at that time showed bismuth held up in the œsophagus, with a moderate degree of dilatation The passage of full sized bougies brought immediate relief He began to put on flesh and soon regained his normal weight The swallowing is still not normal, however Occasionally if he bolts his food it will stick as before, and a recent bereavement brought some increase in the dysphagia He has always more trouble with fluids than with solids, and hot drinks pass down more readily than cold He feels that the drink "meets some wind" in the gullet and at first lies above the wind Then he brings up wind and the food at once goes down into the stomach Examination by X rays showed that the barium was held up for some minutes above the cardia, and that the œsophagus above the barium contained a long column of air Then came a sudden wave of contraction

down the œsophagus and the column of air, acting like a ramrod, seemed to thrust the food on into the stomach At the same time a spasm of the upper sphincter of the œsophagus relaxed and the air was belched up, with an immediate sense of relief to the patient

Ætiology

The condition illustrated by the four cases described above is found, as a rule, in females and arises during early adult life Although there is no well-defined anatomical sphincter at the lower end of the œsoghagus at all comparable with that controlling the pyloric outlet, there can be no doubt as to the presence of a physiological sphincter It is a persistent failure of this cardiac sphincter to relax, both during and after the process of deglutition, that gives rise to these remarkable symptoms Hurst[1] prefers the term cardiac achalasia (or non-relaxation) as being more accurate than cardiospasm He argues that there can be no real spasm, as a mercury tube when once passed can readily be withdrawn without any apparent grip on the part of the sphincter, while in cases that have come to post-mortem examination there is no hypertrophy of the contracted circular muscle-fibres A sphincter, however, that can hold up for an indefinite period a column of food eight or more inches in height, often against the full force of violent peristaltic contractions of the œsophagus, is in a state of highly abnormal tonic contraction, for which I think the older term cardiospasm has much to recommend it

As to the essential cause of the spasm we know as singularly little as is known of the spasm of the upper sphincter, which often precedes the formation of a pouch To describe it as an incoordination of the neuro-muscular control of deglutition only leads us to ask what causes this *incoordination*, and to that question we can as yet give no reply It is necessary to emphasise the point that these patients are by no means of a neurotic or hysterical temperament The theory of Chevalier Jackson that the obstruction is due to a spasm of the right crus of the diaphragm must be rejected, since division of the right phrenic nerve in cases of cardiospasm has failed to affect the obstruction Recorded cases in which degeneration of the vagi has been found are exceptional and atypical Some evidence of hyperæsthesia of the cardiac mucosa may be inferred from the very violent retching that occurred in two of my cases when the mercury tube passed through the sphincter into the stomach Association with pregnancy appeared to have a profound effect in my third case, though the symptoms had been present in some degree for many years It is important in this connexion to note that Vinson[2] has reported from the vast resources of the Mayo Clinic six cases of œsophageal stricture following the vomiting of pregnancy Though his report does not make clear the nature of the stricture in all the cases, it would appear that in some, at any rate, it was spasmodic

Diagnosis and Treatment

The diagnosis is made in part by the clinical history, as the absence of corrosive poisoning will eliminate the ordinary fibrous stricture, while the long duration of symptoms, the greater trouble with fluids than with solids, and the age of the patient will often help to exclude carcinoma The radiographic appearance, however, is characteristic, and should always make the diagnosis plain

Until we know the real cause of the condition *treatment* must be essentially palliative Plummer[3] passes his hydrostatic dilater into the cardia, guided by a previously swallowed thread He has reported a large series of cases with a high proportion of successful results The method, however, is painful, and, according to Hurst, not free from danger The introduction by Hurst of a mercury-filled rubber tube was a real advance in the treatment It should be passed first by the surgeon under the fluorescent screen, and the patient may then pass it herself, at first before each meal, and then at such gradually increasing intervals as the result may demand R P Rowlands, in a case of Hurst's[4] that resisted treatment by his tube, performed a kind of Rammstedt's operation, dividing the muscular coat of the entire cardiac sphincter longitudinally, with a satisfactory result Lambert,[5] in 1914, recorded a case in which he enlarged the œsophageal opening in the diaphragm, drew down part of the dilated œsophagus, and performed an œsophagogastrostomy P. Bull[6] has recently recorded four cases of œsophagogastrostomy by the abdominal route, with very good results It is an operation of severity and considerable risk, and I have so far no personal experience of it, but for the worse type of case in which the spasm will not yield to the simpler method of dilatation by the mercury tube it may acquire an established place in the surgical treatment A simpler procedure, originally advocated by Mikulicz, consists in performing gastrotomy, and dilating the cardia digitally through the open stomach This method has received recent support from Walton,[7] who reported a highly *successful series of cases* Though by no means free from risk, it must be regarded as less dangerous than œsophagogastrostomy Until this method has been tried more widely, and sufficient time has passed to assess the permanence of the relief it affords, a final judgment as to its value must be withheld

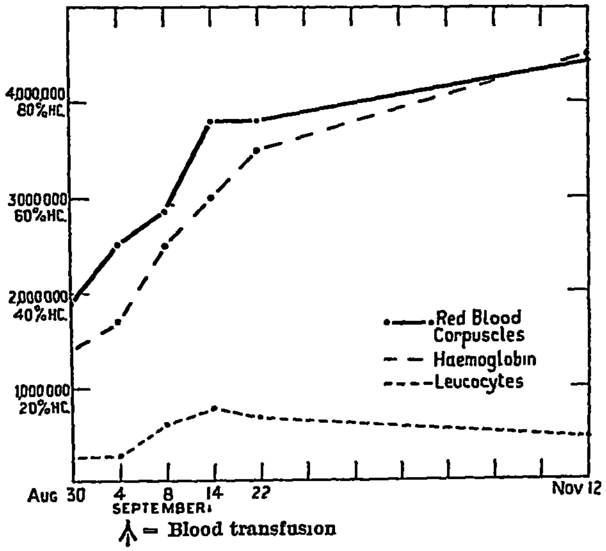
A CASE OF
SEVERE ANÆMIA OF PREGNANCY
SIMULATING ADDISON'S ANÆMIA.

BY T JENNER HOSKIN, M D CAMB, M R C P LOND,
ASSISTANT PHYSICIAN, ROYAL FREE HOSPITAL,
AND
ENID CEIRIOG-CADLE, M B, B S LOND.,
HOUSE PHYSICIAN, ROYAL FREE HOSPITAL.

THIS condition is extremely rare in England, but has been described in the United States, and is not uncommon in Northern India It was first described by Walter Channing in 1842[1] He distinguished it from anæmia due to hæmorrhage, and discussed its dangers, his cases had a high mortality He discussed the possible benefits of blood transfusion. Osler[2] described a severe progressive post-partum anæmia unassociated with hæmorrhage, some cases had high fever suggesting typhoid, but all recovered He found the condition extremely rare in England Larrabee[3] described 15 cases of post-partum anæmia, seven with the secondary type, and eight with the pernicious type of blood picture The secondary anæmias were more common in multiparæ, and all these gave a history of anæmia, hæmorrhage, or definite severe infection associated with previous pregnancies

In five of the cases of the pernicious type the onset was after delivery He found the influence of previous pregnancies was less marked than in the cases of secondary anæmia The cases of pernicious type averaged 22 4 per cent hæmoglobin, with 930,000 red cells, blood cells, and colour-indices from 0 67 to 1 54, in only two cases was the colour-index less than one Abnormal red cells were always present The white cell-count varied *from 10,200* to 1800, averaging 5500; four cases had a relative lymphocytosis Five of these cases had sore mouths and two had fever, in five the spleen was palpable and the liver in two Two premature infants were stillborn, the six full-term babies were perfectly healthy

Larrabee recommends treatment by a single blood transfusion; of his eight cases, the four who had been transfused recovered, whilst three of the others died Smith[4] described eight cases of a pernicious type of anæmia with achlorhydria, associated with pregnancy occurring in women from 18 to 34, including two primiparæ Leucopenia was noted in seven of his cases and stomatitis in three Five of his cases had blood transfusions, and two, of whom one had been transfused, died He recommends repeated blood transfusions and treatment with dilute HCl, as he considers the achlorhydria the main ætiological factor



With regard to prognosis, Galloupe and O'Hara[5] state that the anæmia recurs with increasing severity in later pregnancies, but Larrabee and Osler describe cases of subsequent uncomplicated pregnancies

The ætiology of this condition is obscure Adler[6] considers that the condition occurs in predisposed women, but has no relation to Addison's anæmia Rowland[7] states. "A syncytial hæmolysin is produced in the ectodermal cells of the chorion Later an antihæmolysin is found in the maternal blood, failure in the formation of which results in persistent anæmia" Hein[8] considers Addison's anæmia very rare in pregnancy

Clinical Record

Mrs A B, aged 30, was admitted to hospital on August 28th, 1926, under the care of Dr Hoskin, complaining of fever and pallor

History —Previously a healthy woman, she had lived in India for the last three years, she had never had malaria or other fever, but during the hot weather had had occasional attacks of diarrhœa, with three or four large pale stools a day, such as occur in sprue Four weeks before admission she had a perfectly normal confinement, a full-term healthy baby, and no excessive hæmorrhage For five weeks previously she had complained of breathlessness and great fatigue which was attributed to her pregnancy Fatigue, breathlessness, and pallor increased rapidly after confinement For a week she had been feverish and complained of a heavy feeling in the left axilla, misty vision, and black specks in front of her eyes

Condition on Admission —Temperature, 103° F ; pulse, 130, respirations, 55 Marked pallor, with almost colourless lips and mucous membranes Tongue coated, teeth good, no oral sepsis Abdomen A tender spot opposite the right ninth costal cartilage Liver just palpable, spleen easily palpable; right kidney easily palpable and rather tender Heart Area of cardiac dullness not increased, first sound poor in all areas, and accompanied by soft systolic murmur with maximum intensity at the base of the heart Blood pressure 116 A provisional diagnosis of infective endocarditis was made.

After admission the patient vomited occasionally for three days; on the fourth day the temperature fell to normal The following investigations were carried out

Blood-count —Red cells, 1,870,000, hæmoglobin, 28 per cent; colour-index, 0 8 White cells, 2600, polymorphonuclears, 68 per cent Anisocytosis, poikilocytosis, and diffuse basophile staining were present Normoblasts, megaloblasts, and myelocytes were seen

Fractional Test-meal —Complete achlorhydria

Urine —Specific gravity, 1015 No albumin, sugar and acetone a trace Bile present Urea, 1 3 per cent, total nitrogen, 99 per cent per 100 c cm, urea nitrogen, 0 68 mg per 100 c cm, ammonia nitrogen, 0 030 mg per 100 c cm, urea coefficient, 70 ammonia index, 3 1, diastase, 33 3 There was no indication of kidney or liver inefficiency Van den Bergh's test—positive, delayed, direct and indirect reactions, indicating hæmolysis

Stool —A few red blood-cells No protozoa or excess of streptococci present Retinoscopy (Mr Malcolm Hepburn's report) Several large hæmorrhages in both fundi near the disc No white edges of pigmentation of the hæmorrhages Vessels healthy, except for slight dilatation of the veins The hæmorrhages are retinal in origin and due to a blood rather than to a vascular condition

These findings suggested a severe anæmia of the pernicious type and are similar to those associated with pregnancy as described by Larrabee and C T Smith, and the case was treated on similar lines

Treatment and Progress

Blood Transfusion —500 c cm of blood were transfused by the citrated method on Sept 7th, 1926 Two hours later the patient had a severe rigor, but subsequently her condition improved rapidly Fraise's iron injections—1 c cm was given daily Acid hydrochlor dil in 1 drachm doses was given three times a day in lemonade with meals, this dose was not tolerated owing to development of a sore tongue, and 15-minim doses were given, later this was increased to half a drachm

The general condition improved rapidly, appetite was good The vision improved gradually, the hæmorrhages were slowly absorbed Below is a list of blood counts.

Date in 1926	Red cells	Hb %	Colour-index	White cells	Remarks
Aug 28	1,870,000	28	0 8	2600	On admission.
Sept 4	2,250,000	34	0 8	2800	
,, 8	2,850,000	50	0 9	5760	Day after tf
,, 14	3,840,000	69	0 8	7760	7 days after tf
,, 22	3,880,000	70	0 9	5900	14 days after tf
Nov 12	4,440,000	90	0 1	4440	9 weeks after tf

tf = transfusion

In all counts normoblasts were seen, there was also some anisocytosis and poikilocytosis

Differential Diagnosis

The differential diagnosis was easily made from infective endocarditis by the falling temperature, the blood picture, and absence of signs of infarcts, from secondary anæmia with toxæmia by the blood-count The differential diagnosis from Addison's anæmia was very difficult, the blood picture closely resembled that usually found, but the colour index, though increased, was never so high as is usual in Addison's anæmia, in respects, however, such as the presence of abnormal red cells, the pictures were identical Also this case never showed oral sepsis

The patient made an excellent recovery, although the last blood-count showed the presence of abnormal red blood cells and is indistinguishable from a remission of Addison's anæmia

Conclusions

The occurrence in this disease of severe anæmia, high colour-index, and achlorhydria associates it with Addison's anæmia The symptom of diarrhœa with large pale stools and the incidence of the disease in patients residing in hot climates suggests an infection possibly of the same type as sprue The predisposing factors are undoubtedly achlorhydria associated with general debility, prior to the onset of pregnancy

Our thanks are due to the pathological staff of the Royal Free Hospital who carried out the pathological investigation

FOUR CASES OF ANTHRAX TREATED WITH SCLAVO'S SERUM.

BY R H BOGGON, M B , B S LOND.,
SURGICAL REGISTRAR, ST THOMAS'S HOSPITAL.

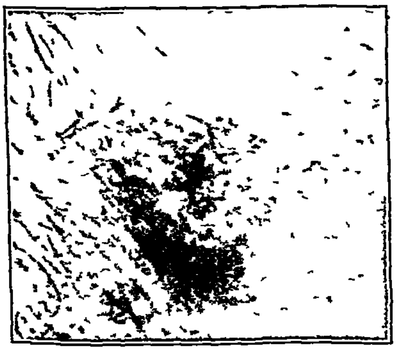
THESE cases of anthrax are of interest inasmuch as they all were traced to the same source of infection—the two elephants which recently died at the Zoo All four men were employed in some connexion with the animals

The diagnosis in each case being made early by the recognition of the *B anthracis* in smears taken from the lesions, immediate serum treatment was undertaken, no active surgery was required All the men made uninterrupted recoveries with the exception of the first who developed broncho-pneumonia following on an attack of influenza

Method of treatment in all cases was subcutaneous injection into the loins or over the glutei of Sclavo's anti-anthrax serum, made at the Tuscan Serum and Vaccine Institute, Siena, and obtained from the London agents, the Jenner Institute for Calf Lymph, Ltd

Details of the cases are as follows —

FIG 1



CASE 1 —Photograph of the lesion taken on the morning of Jan 3rd

CASE 1 —Male, aged 41, a butcher and slaughterman On Christmas Eve he was working, with bare hands and sleeves rolled up above the elbows, on an elephant which has just died at the Zoo Seven days later (Dec. 31st) he noticed a small pimple on his right wrist which was not painful but increased a good deal in size He also felt slight pain in the right axilla but did not feel ill generally On Jan 3rd, 1927, he was admitted to St Thomas's Hospital Temperature, 97° F , pulse, 76 There was a dark elevated sore, ½ in. in diameter, on the radial side of his right wrist (Fig 1) The centre of the sore was black and depressed, no vesicles were present, and there was very slight surrounding œdema Some small glands were just palpable in the axilla but these were not tender Smears taken from the surface of the sore swarmed with *B anthracis*

Twenty c cm of Sclavo's serum were injected subcutaneously into each flank

Jan 4th The lesion had changed considerably The centre was blacker, one or two vesicles had appeared around, and there was some œdema extending about 2 in around the lesion Temperature, 99° Thirty c cm of serum were given

5th Temperature rose to 101° during the night, but dropped again to 99° Lesion appears much the same but less œdema Twenty c cm of serum given

6th Temperature, 97° The lesion beginning to dry up Twenty c cm serum given

10th Temperature, 102 8°, pulse, 100 Patient who had previously been feeling well complained of a sore-throat, a cough, and general aching of the whole of the body No physical signs in the chest The anthrax lesion drying up and scabbing over

In the course of a couple of days the patient showed signs of broncho pneumonia The anthrax lesion was completely scabbed over. On Jan 15th the lesion was scraped and cultures made, but *B anthracis* was not grown. The sputum was also examined for the organism, but this also was negative The chest eventually cleared up and the patient was discharged on Feb 7th, the sore being much smaller with a tough scab over it

CASE 2 —Male, aged 17, horse-keeper On Dec 24th and 28th the patient was employed in carting away the carcasses of two elephants, his arms being bare On Jan 2nd, 1927, he noticed a small pimple on the left side of his face which had not got worse On the 4th he noticed a small pimple on the posterior surface of his forearm He was admitted to St Thomas's Hospital on Jan. 5th Temperature 98 2° F. A small acne pimple was present on the left side of his face, no anthrax bacilli could be found in a smear from this lesion which soon cleared up On the posterior surface of the middle of his right forearm there was a small red pimple not much bigger than a pin's head, which might easily have been called an acne pimple and passed over However, it looked peculiar since it stood alone in the middle of a hairless forearm, with an area immediately around the pimple whiter than the rest Smears showed *B anthracis* in large numbers No glands were palpable Thirty c cm. of serum were given

Jan 6th Spot has slightly increased in size Temperature 98 2° Twenty c cm of serum given

7th Lesion about ¼ in in diameter and of a purple hue, being somewhat darker in the centre No vesicles present but there was a very slight œdema around Epitrochlear gland enlarged Ten c cm of serum given

8th . The condition much the same, except that the lesion was darker in the centre The condition then gradually dried up and scabbed over Cultures made from scrapings on Jan 15th were negative. The patient was discharged on the 17th By Feb 9th the area had healed over

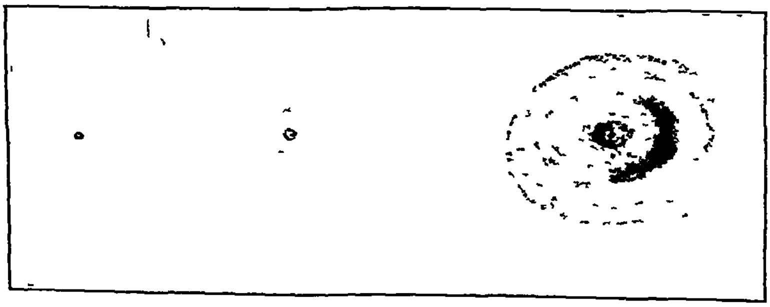
CASE 3 —Male, aged 20, laboratory attendant This patient states that he assisted at the post-mortem on both the elephants and that his hands and forearms were bare while doing so Six days after the second post-mortem (that is on Jan 3rd, 1927) he noticed two small spots on his right forearm These caused some slight irritation but were not painful He was admitted to St Thomas's Hospital on Jan 5th Two lesions were present, one over the subcutaneous border of the ulnar about 3 in from the olecranon, and the other on the middle of the ulnar side of forearm Both resembled the lesion in Case 2 The area immediately around the spots was much whiter than the rest of the forearm and this made them stand out prominently No axillary glands were palpable but the epitrochlear gland was enlarged Forty c cm of serum were given

Jan 6th Spots were slightly bigger and somewhat purple Twenty c cm serum given

7th · Ten c cm serum given The spots had now grown to ¼ in in diameter with a black centre No œdema was present

8th The lesions showed signs of drying up On Jan 15th cultures from the lesions were negative and the patient was discharged on Jan 17th When seen on Feb 15th both sores had healed.

FIG 2

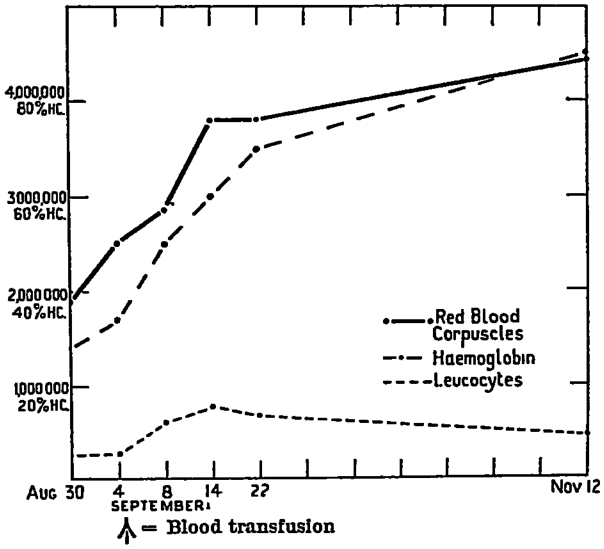


Development of an anthrax pustule Drawings made from Case 2. (Taken, by courtesy of Messrs J and A Churchill from Romanis and Mitchiner's "Science and Practice of Surgery," to be published by them shortly)

These two lesions never looked as bad as the one in Case 2, possibly because of the larger initial dose (40 c cm) of serum given

CASE 4 —Male, aged 27, naturalist This patient was in contact with first elephant only after it had died, working

Larrabee recommends treatment by a single blood transfusion ; of his eight cases, the four who had been transfused recovered, whilst three of the others died Smith [4] described eight cases of a pernicious type of anæmia with achlorhydria, associated with pregnancy occurring in women from 18 to 34, including two primiparæ Leucopenia was noted in seven of his cases and stomatitis in three Five of his cases had blood transfusions, and two, of whom one had been transfused, died He recommends repeated blood transfusions and treatment with dilute HCl, as he considers the achlorhydria the main ætiological factor



With regard to prognosis, Galloupe and O'Hara [5] state that the anæmia recurs with increasing severity in later pregnancies, but Larrabee and Osler describe cases of subsequent uncomplicated pregnancies

The ætiology of this condition is obscure Adler [6] considers that the condition occurs in predisposed women, but has no relation to Addison's anæmia Rowland [7] states "A syncytial hæmolysin is produced in the ectodermal cells of the chorion. Later an antihæmolysin is found in the maternal blood, failure in the formation of which results in persistent anæmia" Hein [8] considers Addison's anæmia very rare in pregnancy

Clinical Record

Mrs A B, aged 30, was admitted to hospital on August 28th, 1926, under the care of Dr Hoskin, complaining of fever and pallor

History —Previously a healthy woman, she had lived in India for the last three years, she had never had malaria or other fever, but during the hot weather had had occasional attacks of diarrhœa, with three or four large pale stools a day, such as occur in sprue Four weeks before admission she had a perfectly normal confinement, a full-term healthy baby, and no excessive hæmorrhage For five weeks previously she had complained of breathlessness and great fatigue which was attributed to her pregnancy Fatigue, breathlessness, and pallor increased rapidly after confinement For a week she had been feverish and complained of a heavy feeling in the left axilla, misty vision, and black specks in front of her eyes

Condition on Admission —Temperature, 103° F, pulse, 130, respirations, 55 Marked pallor, with almost colourless lips and mucous membranes Tongue coated, teeth good, no oral sepsis Abdomen A tender spot opposite the right ninth costal cartilage Liver just palpable, spleen easily palpable, right kidney easily palpable and rather tender Heart Area of cardiac dullness not increased, first sound poor in all areas, and accompanied by soft systolic murmur with maximum intensity at the base of the heart. Blood pressure 116 A provisional diagnosis of infective endocarditis was made.

After admission the patient vomited occasionally for three days, on the fourth day the temperature fell to normal The following investigations were carried out

Blood-count —Red cells, 1,870,000, hæmoglobin, 28 per cent, colour-index, 0 8 White cells, 2600, polymorphonuclears, 68 per cent Anisocytosis, poikilocytosis, and diffuse basophile staining were present Normoblasts, megaloblasts, and myelocytes were seen

Fractional Test-meal —Complete achlorhydria

Urine —Specific gravity, 1015 No albumin, sugar and acetone a trace Bile present Urea, 1 3 per cent, total nitrogen, 99 per cent per 100 c cm, urea nitrogen, 0 68 mg per 100 c cm, ammonia nitrogen, 0 030 mg per 100 c cm, urea coefficient, 70 ammonia index, 31, diastase, 33 3 There was no indication of kidney or liver inefficiency Van den Bergh's test—positive, delayed, direct and indirect reactions, indicating hæmolysis

Stool —A few red blood-cells No protozoa or excess of streptococci present Retinoscopy (Mr Malcolm Hepburn's report) Several large hæmorrhages in both fundi near the disc No white edges of pigmentation of the hæmorrhages Vessels healthy, except for slight dilatation of the veins The hæmorrhages are retinal in origin and due to a blood rather than to a vascular condition

These findings suggested a severe anæmia of the pernicious type and are similar to those associated with pregnancy as described by Larrabee and C T Smith, and the case was treated on similar lines

Treatment and Progress

Blood Transfusion —500 c cm of blood were transfused by the citrated method on Sept 7th, 1926 Two hours later the patient had a severe rigor, but subsequently her condition improved rapidly Fraise's iron injections—1 c cm. was given daily Acid hydrochlor dil in 1 drachm doses was given three times a day in lemonade with meals, this dose was not tolerated owing to development of a sore tongue, and 15-minim doses were given, later this was increased to half a drachm

The general condition improved rapidly, appetite was good The vision improved gradually, the hæmorrhages were slowly absorbed Below is a list of blood counts

tf = transfusion

In all counts normoblasts were seen, there was also some anisocytosis and poikilocytosis

Differential Diagnosis

The differential diagnosis was easily made from infective endocarditis by the falling temperature, the blood picture, and absence of signs of infarcts, from secondary anæmia with toxæmia by the blood-count The differential diagnosis from Addison's anæmia was very difficult, the blood picture closely resembled that usually found, but the colour index, though increased, was never so high as is usual in Addison's anæmia, in respects, however, such as the presence of abnormal red cells, the pictures were identical Also this case never showed oral sepsis

The patient made an excellent recovery, although the last blood-count showed the presence of abnormal red blood cells and is indistinguishable from a remission of Addison's anæmia

Conclusions

The occurrence in this disease of severe anæmia, high colour-index, and achlorhydria associates it with Addison's anæmia The symptom of diarrhœa with large pale stools and the incidence of the disease in patients residing in hot climates suggests an infection possibly of the same type as sprue The predisposing factors are undoubtedly achlorhydria associated with general debility, prior to the onset of pregnancy.

Our thanks are due to the pathological staff of the Royal Free Hospital who carried out the pathological investigation

obstruction and was rushed to the Royal Victoria Hospital, Montreal. Dr F. A. C Scrimger, who operated, reported —

"On opening the abdomen a large sac-like portion of the intestine was found, and round the base of this was twisted the cæcum and a long appendix, forming a volvulus, obstructing the small intestine for about one foot on either side of the Meckel's diverticulum" (see figure)

There were a few enlarged mesenteric glands opposite the diverticulum. The pathologist reported that the diverticulum was 6 cm. long and 4 cm. in diameter

Since operation the stools have no longer been huge; there has been no abdominal pain or vomiting, no constipation, no disinclination for food, and no rise of temperature without obvious cause. After convalescence the child did, however, suffer from repeated attacks of tonsillitis, and her tonsils were enucleated in February, 1925 The effect of her release, as I interpret it, from chronic intoxication (bowel and/or tonsils) affords a striking picture Since the symptoms of toxæmia, when they became acute (i.e., temperature 103 8°), were always dispersed at once by laxatives, and since she had only had two sore-throats in her life and her tonsils and cervical glands appeared normal, I feel certain that the origin of the toxæmia was not tonsillar, but was more likely to have been in the alimentary tract.

If in this case more attention had been paid to the character of the stools, and to the fact that periodical pain occurred in a negative abdomen, and if a radiographic examination had been made, the diagnosis might have been reached before the catastrophe of intestinal obstruction.

A CASE OF

LYMPHOSARCOMA OF THE NASO-PHARYNX TREATED WITH RADIUM AND X RAYS.

BY HECTOR A. COLWELL, M.B, M R C P. LOND, D.P H. OXF.,

DIRECTOR OF THE RADIOLOGICAL DEPARTMENT, KING'S COLLEGE HOSPITAL.

THE following case seems worthy of record as one in which an extensive lymphosarcoma disappeared under radiation therapy, without any operative procedure other than that necessary for the application of radium, and in which no recurrence has occurred during a period of over six and a half years Lymphoid tissue and lymphosarcoma are, of course, eminently sensitive to X rays and to the radiations from radium, but the tendency of lymphosarcomata to the formation of early and extensive metastases too often militates against a successful issue when treatment is undertaken

When first seen in September, 1920, the patient was a thin and somewhat cachectic man 31 years of age, who attended the hospital complaining of obstruction in the nose, bleeding from the back of the nose (into the pharynx) of some four weeks' duration, and gradually increasing deafness

Examination showed hyperplastic rhinitis with enlargement of the posterior extremities of the inferior turbinate bones, while the inferior meatus on both sides was filled with gelatinous mucus The nasopharynx was occupied by a large bluish-red mass showing evidence of recent hæmorrhage A further large mass occupied the area behind the posterior pillar of the fauces on the left side and extended to the Eustachian cushion, while a similar, but somewhat smaller, mass was present on the right side On both sides the glands in the posterior triangle of the neck were enlarged and indurated, the condition being more marked on the left side A portion of the growth was removed for histological examination and the clinical diagnosis of neoplasm was confirmed by the report that the specimen showed lymphosarcoma

Treatment and Course—The condition was so extensive as to be quite inoperable and it was decided to employ radiation therapy as a palliative measure, since the condition of the primary growth, with the coincident glandular involvement, seemed to hold out but little hope of a permanent cure being effected.

Accordingly, on Sept 22nd 1920 Mr C W. M Hope inserted two 50 mg. tubes of radium bromide, one into the main nasopharyngeal neoplasm and the other into the mass on the left side Both tubes were left in situ for six hours Five days later (Sept 27th) X ray treatment was commenced, one Sabouraud pastille dose being administered through a 3 mm. aluminium filter to both sides of the neck, the rays being directed upwards and inwards towards the nasopharyngeal region.

On Oct 1st the condition had much improved and the symptoms become markedly alleviated, breathing through the nose being comparatively easy, while the deafness was diminished. On Oct 5th the X ray treatment was repeated and five days later (Oct 10th) radium was again inserted for six hours, as before, into the already much shrunken growth At the same time the enlargement and induration of the cervical glands was found to be considerably diminished. On Oct 19th the postnasal space was—so far as macroscopic evidence was concerned—found to be free of growth.

Ten further applications of X rays were given between Oct. 19th, 1920, and March 29th, 1921. The nasopharynx remained free of growth and the glandular induration and enlargement completely disappeared There was now no apparent scope for any operative measures, and the patient has been kept under observation from 1921 until the present time. There is now, six and a half years after the initial treatment, no evidence of either primary growth or metastases The patient appears well and healthy, with only a few telangiectases on the neck due to the X ray treatment.

The patient came to the nose and throat department of King's College Hospital under the care of Mr. Hope, to whose kindness I am indebted for permission to publish the present note and by whom the insertion of the radium was undertaken.

A CASE OF

RUPTURE OF AN ENLARGED MALARIAL SPLEEN

BY JOHN MACQUEEN, M B, B CH. EDIN.,

ASSISTANT PRINCIPAL MEDICAL OFFICER, JERUSALEM

RUPTURE of a chronically enlarged spleen is not an uncommon accident in countries where malaria is prevalent. The condition is a grave one and the surgeon on opening the abdomen is faced with the removal of the organ. There appears at first to be nothing else to do, for stitching is generally useless, and the bleeding must be controlled by some means. Splenectomy of a malarial spleen is at any time a serious operation A surgical colleague in Egypt who removes enlarged spleens assured me recently that removal of the enlarged malarial spleen was followed by 100 per cent. mortality. The literature does not put it so high as this, but few surgeons, I should imagine, practise splenectomy to any extent, and it is probable that the experience quoted is, in this respect, as wide as that of most people The following case seems, therefore, worth reporting.

A male patient, aged 15, was admitted to the Municipal Hospital at Jaffa on Nov 17th, 1926. He walked from a carriage at the hospital entrance into the reception room.

History—He stated that he had come from Damascus to Jaffa recently to work with his uncle. On the day of admission, an hour before, this relative had kicked him on the abdomen. He collapsed after the blow and on coming to felt great pain in the abdomen, vomited once, and was brought to the hospital by the police. There was a history of recurrent attacks of fever in Damascus

Examination.—He was slightly, pale and had the rather muddy tint of the sufferer from malaria He complained of pain in the upper abdomen and walked half bent forward. The pulse-rate was 104 and the temperature 37 5 C The abdomen moved with respiration but in a forced and unnatural manner, and was arrested by sharp pain on three-quarters inspiration. I received the impression that this arrest was due to a diaphragmatic lesion. There was some tenderness in the left hypochondrium No movable dullness in the flanks could be demonstrated. There was no evidence of fracture of any of the ribs and the patient did not appear very ill. The spleen could not be palpated.

Rupture of the spleen was considered as a possible diagnosis and he was kept under close observation. On the 18th he was no worse On the 19th the temperature was 39 C., the pulse-rate had increased to 120, and the abdomen, [illegible], moved with respiration. I was unable to demonstrate movable dullness in the flanks. At the left base there with bare arms which became smeared with blood A week later he noticed an irritable pimple on his left arm, he scratched it and the arm became painful and red A smear at this stage showed no anthrax bacilli, but did show staphylococci and streptococci Hot fomentations were given, but the inflammation still spread On Jan 9th a 24 hours' culture showed *B anthracis* sporing, with heavy staphylococcal and streptococcal infection Fifteen c cm of serum (Parke, Davis) had been given the day before

On admission the patient did not look at all fit Temperature, 104 2° F, pulse, 106, tongue dirty A pustule was present on the radial side of the flexor surface of the forearm 3 in above the wrist It was about one-third inch in diameter, with a black centre and purple periphery Around all this was an acute cellulitis and lymphangitis ascending the forearm as far as the elbow The epitrochlear gland was enlarged and also the axillary glands A dose of 30 c cm of serum was given and hot dressings applied

Jan 8th Temperature, 103 4°, pulse, 96 The lesion appeared much the same Thirty c cm of serum given

9th. Temperature, 99 4°; pulse, 80 Is much better in himself The actual lesion is slightly larger but the lymphangitis is less Twenty c cm of serum given

10th Ten c cm of serum given The cellulitis and lymphangitis gradually cleared up without suppuration and the pustule gradually scabbed over No anthrax bacilli were found in a culture on Jan 15th, and patient was discharged on the 17th

When he was seen on Feb 16th the actual site of the pustule had not quite healed

Comments

The incubation period of all these cases lay between six to seven days, this shows the necessity of watching contacts over a period in excess of a week

In the early stages, as shown by Cases 2 and 3, the anthrax pustule bears little resemblance to the lesion described in text-books It is only when the pustule has become well developed that the classical appearance is produced (Fig 2) These lesions could only be distinguished clinically from a septic spot by the history, the dark centre, and the area of whiteness immediately around It is noteworthy that when bacilli were to be found in smears they were always present in large numbers The first smear from Case 4 was negative, but here there was a heavy secondary infection

No surgery was contemplated since all these cases reacted so well to serum The largest total dosage of serum was given in the first case (110 c cm) and the least in the second case (60 c cm) The latter however, flared slightly and perhaps a little more serum was indicated The fourth case was the worst constitutionally because of the cellulitis but this soon settled down with rest and heat All the sores took a long time to heal completely over, although no anthrax bacilli were present after Jan 15th

I am much indebted to Mr C Max Page and Mr. P H Mitchiner for permission to record these cases

LIVERPOOL STUDENTS' COLLECTION FOR HOSPITALS The students of Liverpool University at their annual "rag" collected £5200 for the local hospitals, which is £1400 more than the previous best collection, and represents an average of £4 per collector

PROGRESS OF GLASGOW HOSPITALS —At the annual meeting of Glasgow Royal Infirmary an expenditure of £65,000 upon extensions was authorised The enlargements will include a lecture theatre commemorative of Lord Lister who was closely connected with the infirmary from 1861 to 1869 Further relief from pressure upon the wards is to be sought by the erection of an auxiliary hospital Meanwhile, the out-patient department and the Ophthalmic Institution are described as entirely inadequate —The annual report of Glasgow Western Infirmary states that the accommodation for the X ray and electrical department is practically the same as when the out-patient department was built 20 years ago, and this part of the work is being carried out with great difficulty A completely new X ray department is, indeed, needed —A new wing and an extension of the nurses' home are nearly completed, the entire cost of the works is estimated at £100,000 A new auxiliary hospital is to cost £50,000 —The David Elder Infirmary at Govan, built by the Elder Trustees, will be completed in a few months and handed over, with some £60,000 as the nucleus of an endowment fund, to the Western Infirmary

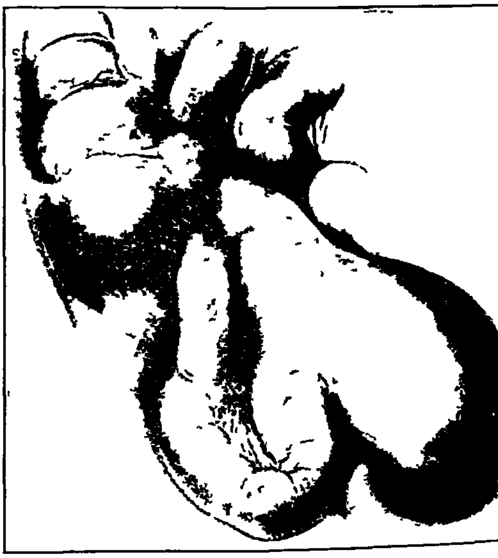
Clinical and Laboratory Notes.

A CASE OF MECKEL'S DIVERTICULUM*

BY C S McEUEN, M D, C M McGILL.

THE following case shows the nearly disastrous result of my failure to interpret signs and symptoms

The patient was a girl aged 7½ years During babyhood she occasionally had attacks of slight fever, with symptoms of intestinal toxæmia, which always cleared up with grey powder She was constipated and often vomited I took over the case in 1923, and found the child small (weight 28 lb), with poor muscular development, thin, looking very frail, and easily tired on exertion Night sweats were so excessive that her nurse raised the question of enuresis The girl never wished to eat Attacks of vomiting occurred three to four times a month, often during meals, but then never until she had eaten a considerable quantity of food, which she used suddenly to vomit, without more than three minutes preceding nausea



Condition seen at operation

Constipation was a constant trouble The stools were often very big in quantity, and of alarmingly large calibre, I should say 1½ to 2 in. in diameter was the rule She persistently felt tired and often had a temperature without apparent cause This, however, always yielded to a laxative

On six to eight occasions during the year 1923–24 the girl was observed to suddenly stop playing, sit very still, turn pale, and look frightened On being asked what was the matter she used to say she had "her pain" and point to the umbilicus She said that the pain "was not really a bad one" and it did not last over one minute It was never accompanied by vomiting Usually she sat very still for about one minute and then went on playing as if nothing had happened On many of these occasions she was at once undressed and I examined the abdomen carefully, but I never could detect any abnormality beyond a slight flatulent distension It is true that by the time the child was undressed she said the pain had gone and, therefore, the examinations were made too late

In August, 1924, I crossed to Canada with her She had an attack of acute tonsillitis on board ship which, to the best of her father's memory, was only the second sore-throat that she had ever had The child then spent three weeks with me in the Laurentian Mountains One day she complained of tiredness all day and refused food I found her temperature 103 8° F A physical examination was negative, except for a slight flatulent distension of the abdomen She was given in all 1½ drachms of cascara evacuant, her bowels moved in 22 hours with a characteristically enormous stool, when her temperature had fallen to 98 8°, and the next morning she was in her usual health About ten days later the child suddenly developed an acute intestinal obstruction and was rushed to the Royal Victoria Hospital, Montreal Dr F A C Scrimger, who operated, reported :—

---

* Abridged from a report read to the James Mackenzie Institute, St Andrews, on April 23rd, 1926

"On opening the abdomen a large sac-like portion of the intestine was found, and round the base of this was twisted the cæcum and a long appendix, forming a volvulus, obstructing the small intestine for about one foot on either side of the Meckel's diverticulum" (see figure)

There were a few enlarged mesenteric glands opposite the diverticulum. The pathologist reported that the diverticulum was 6 cm. long and 4 cm. in diameter

Since operation the stools have no longer been huge; there has been no abdominal pain or vomiting, no constipation no disinclination for food, and no rise of temperature without obvious cause. After convalescence the child did, however, suffer from repeated attacks of tonsillitis and her tonsils were enucleated in February. 1925 The effect of her release, as I interpret it, from chronic intoxication (bowel and/or tonsils) affords a striking picture Since the symptoms of toxæmia, when they became acute (i e, temperature 103 8°), were always dispersed at once by laxatives and since she had only had two sore-throats in her life and her tonsils and cervical glands appeared normal, I feel certain that the origin of the toxæmia was not tonsillar, but was more likely to have been in the alimentary tract.

If in this case more attention had been paid to the character of the stools, and to the fact that periodical pain occurred in a negative abdomen. and if a radiographic examination had been made the diagnosis might have been reached before the catastrophe of intestinal obstruction.

A CASE OF

LYMPHOSARCOMA OF THE NASO-PHARYNX TREATED WITH RADIUM AND X RAYS

BY HECTOR A COLWELL, M B, M R C P. LOND., D P H OXF,
DIRECTOR OF THE RADIOLOGICAL DEPARTMENT, KING'S COLLEGE HOSPITAL.

THE following case seems worthy of record as one in which an extensive lymphosarcoma disappeared under radiation therapy, without any operative procedure other than that necessary for the application of radium, and in which no recurrence has occurred during a period of over six and a half years Lymphoid tissue and lymphosarcoma are of course, eminently sensitive to X rays and to the radiations from radium, but the tendency of lymphosarcomata to the formation of early and extensive metastases too often militates against a successful issue when treatment is undertaken

When first seen in September, 1920, the patient was a thin and somewhat cachectic man 34 years of age, who attended the hospital complaining of obstruction in the nose, bleeding from the back of the nose (into the pharynx) of some four weeks' duration, and gradually increasing deafness

Examination showed hyperplastic rhinitis with enlargement of the posterior extremities of the inferior turbinate bones, while the inferior meatus on both sides was filled with gelatinous mucus The nasopharynx was occupied by a large bluish-red mass showing evidence of recent hæmorrhage A further large mass occupied the area behind the posterior pillar of the fauces on the left side and extended to the Eustachian cushion, while a similar, but somewhat smaller, mass was present on the right side On both sides the glands in the posterior triangle of the neck were enlarged and indurated, the condition being more marked on the left side A portion of the growth was removed for histological examination and the clinical diagnosis of neoplasm was confirmed by the report that the specimen showed lymphosarcoma.

Treatment and Course—The condition was so extensive as to be quite inoperable and it was decided to employ radiation therapy as a palliative measure, since the condition of the primary growth with the coincident glandular involvement, seemed to hold out but little hope of a permanent cure being effected

Accordingly on Sept 23rd 1920 Mr C W M Hope inserted two 50 mg tubes of radium bromide, one into the main nasopharyngeal neoplasm and the other into the mass on the left side Both tubes were left *in situ* for six hours Five days later (Sept 28th) X ray treatment was commenced, one Sabouraud pastille dose being administered through a 3 mm. aluminium filter to both sides of the neck, the rays being directed upwards and inwards towards the nasopharyngeal region.

On Oct. 1st the condition had much improved and the symptoms become markedly alleviated, breathing through the nose being comparatively easy, while the deafness was diminished On Oct 5th the X ray treatment was repeated and five days later (Oct. 10th) radium was again inserted for six hours, as before, into the already much shrunken growth. At the same time the enlargement and induration of the cervical glands was found to be considerably diminished. On Oct. 19th the postnasal space was—so far as macroscopic evidence was concerned—found to be free of growth.

Ten further applications of X rays were given between Oct 19th 1920, and March 29th, 1921. The nasopharynx remained free of growth and the glandular induration and enlargement completely disappeared. There was now no apparent scope for any operative measures. and the patient has been kept under observation from 1921 until the present time There is now, six and a half years after the initial treatment no evidence of either primary growth or metastases The patient appears well and healthy, with only a few telangiectases on the neck due to the X ray treatment.

The patient came to the nose and throat department of King's College Hospital under the care of Mr Hope, to whose kindness I am indebted for permission to publish the present note and by whom the insertion of the radium was undertaken

---

A CASE OF

RUPTURE OF AN ENLARGED MALARIAL SPLEEN.

BY JOHN MACQUEEN. M.B, B CH EDIN,
ASSISTANT PRINCIPAL MEDICAL OFFICER, JERUSALEM

RUPTURE of a chronically enlarged spleen is not an uncommon accident in countries where malaria is prevalent. The condition is a grave one and the surgeon on opening the abdomen is faced with the removal of the organ There appears at first to be nothing else to do, for stitching is generally useless, and the bleeding must be controlled by some means. Splenectomy of a malarial spleen is at any time a serious operation A surgical colleague in Egypt who removes enlarged spleens assured me recently that removal of the enlarged malarial spleen was followed by 100 per cent mortality. The literature does not put it so high as this but few surgeons I should imagine practise splenectomy to any extent, and it is probable that the experience quoted is in this respect, as wide as that of most people The following case seems therefore, worth reporting

A male patient, aged 15, was admitted to the Municipal Hospital at Jaffa on Nov 17th, 1926 He walked from a carriage at the hospital entrance into the reception room

History—He stated that he had come from Damascus to Jaffa recently to work with his uncle. On the day of admission, an hour before, this relative had kicked him on the abdomen. He collapsed after the blow and on coming to felt great pain in the abdomen, vomited once, and was brought to the hospital by the police There was a history of recurrent attacks of fever in Damascus

Examination—He was slightly pale and had the rather muddy tint of the sufferer from malaria. He complained of pain in the upper abdomen and walked half bent forward The pulse-rate was 104 and the temperature 37 5° C The abdomen moved with respiration but in a forced and unnatural manner, and was arrested by sharp pain on three-quarters inspiration. I received the impression that this arrest was due to a diaphragmatic lesion. There was some tenderness in the left hypochondrium No movable dullness in the flanks could be demonstrated. There was no evidence of fracture of any of the ribs and the patient did not appear very ill. The spleen could not be palpated.

Rupture of the spleen was considered as a possible diagnosis and he was kept under close observation. On the 18th he was no worse On the 19th the temperature was 38° C the pulse-rate had increased to 120, and the abdomen scarcely moved with respiration I was unable to demonstrate movable dullness in the flanks. At the left base three was lessened air-entry and a few râles The patient looked ill It was decided that laparotomy should be performed

Operation —A central incision above the umbilicus revealed blood in the abdomen. Examination of the spleen by the hand—it is not possible to deliver these enlarged spleens through a central incision—showed a tear about half an inch wide running across the lateral surface and continuing round to and across the medial surface The organ was much enlarged, being about 11 in. long and firmer than normal The incision was carried across to the left flank with the intention of performing splenectomy

Recalling, however, the advice of my colleague, and the patient's condition being none too good, I felt that if possible something less radical must be tried Stitching was attempted, but proved useless There was evidence at this stage of a rupture of the diaphragm at the upper pole of the spleen. Air was blowing out and in with respiration It was decided to try packing This was done by means of five pieces of gauze each about 70 c cm long Three were pushed up on the lateral and two on the medial sides of the organ, the last two respectively in front and behind the hilus The spleen appeared to be quite tightly and fairly uniformly compressed in this way, and the lacerations were covered. Some blood was swabbed out of the abdomen and the wound closed with through-and-through silkworm-gut sutures except at the lateral corner where the five ends of gauze were left out

Progress —After operation the pulse was 122 and weak, and the temperature 38° C One pint of saline was given subcutaneously and later ⅙ gr of morphine hydrochloride On the second day the temperature dropped to normal and although the pulse remained rapid the patient did remarkably well On the third day after operation the gauze was carefully removed and the wound completely closed On the eighth to eleventh days after operation the temperature rose, the corner of the wound reopened, and pus discharged Otherwise there were no complications and the patient left hospital 26 days after operation.

Packing for rupture of the spleen is mentioned in the literature, but I had not heard of it before In publishing this case my object is to obtain, if possible, the experience of others working in countries where malaria prevails If this line of treatment holds out a fair hope of success it is, I should think, sounder than splenectomy for such cases

I am extremely indebted to Dr F Dejani, of the Municipal Hospital, Jaffa, for his assistance in this case

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF DERMATOLOGY

At a meeting of this Section held on Feb. 18th, Dr E **Graham Little** in the chair, a discussion took place on the

Treatment of Ringworm by Thallium Epilation

Dr E B **Dowling** demonstrated four cases of the series reported in The Lancet last week (page 389) Three of them were showing active regrowth after complete epilation, the fourth was of later date and had not yet reached total defluvium This child had complained of pains in the legs a week after taking his dose of thallium acetate, but had completely lost the symptom a few days later Dr Dowling thought that these undesirable effects might be diminished or even prevented by keeping the patients in bed whilst epilation is taking place—i e , for about three weeks

Dr S **Monckton Copeman** related personal experiences of the use of thallium acetate in the treatment of inoperable carcinoma The patients' ages, he said, varied from 49 to 78, and the cases could not therefore be fairly compared with those under discussion A solution of the salt, prepared and tested by Prof W E Dixon of Cambridge, was administered intramuscularly, at first on alternate days in doses of 1 grain then every day, then in doses of 2 gr on alternate days. and finally in doses of 1 gr every other day The total amounts injected during an average period of three weeks varied from 0 778 to 1 361 grammes, thus a proportionately much greater dose had been given than in any of the cases reported by Dr Dowling This dose was, however, spread out over three weeks instead of being given in one draught as the object was to obtain, if possible, a continuous inhibitory effect on the neoplasms Some improvement had, in fact, been noted Five of the six cases treated had lost all their scalp hair, two of them even their eyebrows and lashes The only one who did not suffer in this respect—a man of 49—had developed mental symptoms of a delusional type after only 0 778 g had been administered, and in his case, therefore, the drug had had to be discontinued He had subsequently recovered his normal mentality. All the cases had complained of tingling pain in the limbs and a burning sensation in the soles of the feet In two of them colicky abdominal pains developed but no diarrhœa Albuminuria did not occur. One woman, aged 70, who had advanced malignant disease of the breast, had complained of severe substernal pain in addition to the other symptoms cited above In her case injections were stopped at once after 1 037 g had been given, but she died three days later from sudden heart failure without developing any other noteworthy symptoms There were no very definite post-mortem findings, except the secondary deposits, to account for her death It was to be presumed, therefore, that the thallium was at least a contributory cause

Dr H. W. **Barber** called attention to the interesting similarity of the epilation produced by thallium acetate, X rays, and alopecia areata, in all of which atrophic "exclamation stumps" were to be found He also remarked on the persistence of a frontal fringe of non-epilated hair in Dr Dowling's cases, which he regarded as some evidence of a selective affinity for different areas He agreed with the view expressed by Buschke, Peter, and others, that thallium acetate probably acted by way of the sympathetic nervous system and only indirectly on the hair

Dr H C **Semon** said that he had noted very similar toxic phenomena during the intravenous injections of a gold salt (krysolgan), with which he was treating cases of lupus erythematosus The pains of which his patients had complained were sharp and fleeting, and suggested in their distribution an affection of fibrous sheaths round muscles He had quite recently discovered that an intravenous injection of 0 6 g of thiosulphate of soda appeared to exercise a rapid and very effectual control of the symptom, acting in much the same way as he had described for the toxæmias of bismuth and mercury The atomic weights of gold (197 2), and thallium (204), were closely similar, and it might conceivably be found that the antidotal effects of thiosulphate of soda would be useful in preventing or alleviating undesirable results from the administration of thallium

MANCHESTER MEDICAL SOCIETY.

At a meeting of this Society held on Feb 2nd, Dr A A. **Mumford** in the chair, Dr R I **Poston** opened a discussion on

Vertigo

He dealt first with the occurrence of vertigo in epidemic encephalitis (encephalitis lethargica) where, he said, this symptom often appeared in association with other signs of vestibular disorder Recalling Gertier's "paralysing vertigo" of 1888, he went on to describe the endemic kubisagari of Japan The two affections had much in common, and there could be little doubt that they were variants of the same condition There could be no doubt that they were both due to an infective encephalitis, and he suggested that as kubisagari had occurred in Japan up to 1912, it was possible that it was responsible, or that undiagnosed cases of Gertier's disease in Europe were responsible, for the pandemic of the last decade

An outbreak of encephalitis with vestibular symptoms had been reported in Strasbourg in 1921

Having dealt with the known pathology of the condition and the results of several experimental workers who had actually found vestibular lesions in rabbits, Dr Poston gave a brief description of six cases of encephalitis which had come under his own care With Mr F H Diggle's help the vestibular reaction of these cases had been determined and abnormal induced nystagmus had been found in three In a case in which there was complete external ophthalmoplegia (seen through the kindness of Prof A J Hall, of Sheffield) it had been found that simple syringing of the ears with cold water not only relieved ptosis, but enabled the patient to move his eyeballs in every direction and relieved the diplopia of which he complained He described another case of Prof Hall's which showed "spasmodic cramp of the upward glance," and in which change of position changed the direction, but not the character of the phenomenon

Discussing the diagnosis of vestibular encephalitis, Dr Poston urged the importance of first excluding cerebro-spinal syphilis, aural disease, and intracranial lesions He pointed out that in cases of epidemic encephalitis with gross signs of cerebellar involvement it had been found at autopsy that the cerebellum was normal Nystagmus might suggest disseminated sclerosis unless definite and incontestible signs of Parkinsonism were present The following triad was suggested as offering clinical evidence of disordered vestibular function in the absence of aural disease: disorders of equilibration (e g , vertigo), spontaneous nystagmus, and abnormal induced nystagmus or abnormal Babinski-Weill reactions

Dr Poston suggested a classification of epidemic encephalitis as follows (1) vestibular syndrome; (2) juxta-vestibular syndrome with signs pointing to involvement of structures adjacent to or connected with the vestibular nucleus, such as oculomotor symptoms, neuralgia, facial paralysis, sialorrhœa, disorders of respiration and pulse, or dysphagia, (3) pallidal syndrome—e g , tremor and rigidity; (4) striate syndrome—e g , tremor and myoclonus Pyrexia and lethargy were the only common symptoms not included in such a classification In conclusion, he stated that the vestibular syndrome in epidemic encephalitis might occur alone or with such symptoms as those already mentioned, it might occur at the onset, during the acute stage of the disease, or it might persist as a residuum Interference with vestibular function might account for many of the oculomotor phenomena of the disease, if not for all of them

Mr F H **DIGGLE**, after briefly referring to the fact that vertigo was only one manifestation of a disturbance of the vestibular apparatus, pointed out that by artificial stimulation of the peripheral sense-organ in the labyrinth it was possible to produce all the symptoms and signs of such a disturbance—viz , vertigo, nystagmus, reeling gait, and vomiting He further showed that by a close study of such induced symptoms it was possible not only to test the integrity of the peripheral end-organ, the labyrinth, but also, in a few cases, to locate a lesion in other parts of the vestibular nervous arc Vertigo, he said, might be produced by a lesion in the labyrinth, by a lesion in its intracranial and spinal connexions, or by ocular lesions Vertigo arising in acute inflammatory conditions of the middle ear was usually relieved by efficient paracentesis tympani He drew attention, however, to the prevalence and seriousness of vertigo in acute exacerbations in chronic suppuration in the ear The danger lay in the fact that translabyrinthine infection was the commonest precursor of fatal meningitis, and the warning signal of vertigo should not be neglected

Discussing non-suppurative labyrinthine lesions, Mr Diggle referred to the difficulty arising from the want of pathological knowledge Vertigo might be due to abnormal pressure of the intralabyrinthine fluids, to irregularities in the vascularity of the organ, or to the effects of toxins upon the nerve end-organ He thought that vertigo associated with impacted ceruminous plugs, intermittent Eustachian obstruction, and occasionally hydrops of the middle ear could be explained by abnormal intralabyrinthine pressure Increased pressure of cerebro-spinal fluid might directly raise intralabyrinthine pressure and so produce vertigo, though often cerebral anæmia could not be excluded Relief occasionally followed lumbar puncture, and a few cases had been recorded by Aboulker and Colledge in which relief had followed the operation of subtentorial decompression In dismissing intralabyrinthine pressure Mr Diggle mentioned cases recorded by Mollison of relief to vertigo after trephining the external semicircular canal

In considering vascular lesions affecting the labyrinth, Mr Diggle drew attention to the fact that many patients on examination presented a normal inner ear Massive hæmorrhage as a cause of the Ménière's syndrome was, he thought, infrequent, though it could not be denied that there were sometimes small leakages from atheromatous vessels Other remote lesions, apart from intralabyrinthine hæmorrhage—such as arterio-sclerosis, abnormal blood pressure, certain anæmias, metabolic disorders, and toxins—might be responsible for Ménière's syndrome Was vertigo in such cases due to effusion into the labyrinth, to atheromatous disease of the vessels, or to toxic neuritis? Mr Diggle pointed to the analogy in the eye—namely, tobacco amblyopia, retinal hæmorrhages in nephritis, and retinal detachments from effusion—and drew attention to the toxæmic conditions responsible for vertigo and to the frequent association of vertigo with nicotine poisoning and with nasal sinus suppuration. He considered that occult sepsis was a potent factor. In discussing treatment he urged that no operative ablation of the labyrinth should be undertaken until all other measures had failed, and then only on a labyrinth functionally inactive

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

THE annual meeting of this Society was held at Manchester on Jan 28th

Dr W R **ADDIS** read a paper on a

New Method of Inducing Labour.

The method, he said, consisted in the intramuscular injection of extract of ovarian residue (without corpus luteum) prepared by Parke Davis and Co The amount given was 1 c cm of the extract, and this was injected into the pectoralis major muscle, where it formed the anterior border of the axilla At first the contractions of the uterus had to be recognised by palpation as the onset of labour was painless The dose was repeated when the contractions began to diminish in intensity and frequency The average time in which this occurred was about three hours After the second injection a dose of one ounce of castor oil was given by mouth. Dr Addis had employed this method in 22 cases at stages of pregnancy varying from 36 weeks to a week post-mature He had come to the conclusion that it was practically infallible as a method of induction of labour Only in the first case had the method been a partial failure. With this form of induction the labour induced was almost painless throughout the first and beginning of the second stage. and pains were really only experienced when the presenting part caused bulging of the perineum

Dr J W **BURNS** (Liverpool) showed a specimen of an

Unusual Uterine Tumour

The patient was a woman, aged 39, whose menstrual history was not abnormal until 18 months before she came under observation, when the loss began to increase For the past month there had been more or less constant bleeding, and she complained of weakness There were no symptoms arising from either the bladder or rectum

On *examination* a smooth, hard tumour could be felt in the lower abdomen reaching almost to a point midway between the symphysis pubis and the umbilicus Bimanually the cervix was found to be drawn up behind the pubes and the uterus was enlarged, hard, smooth, and freely mobile There was no swelling of the appendages A diagnosis of fibroid was made

At *operation*, on the peritoneum being opened some free dark blood was seen The uterus was symmetrically enlarged by what was thought to be a fibroid undergoing some degeneration Portions of the sigmoid and the ileum were adherent to the upper surface of the tumour, they were liberated with difficulty and a subtotal hysterectomy was done with removal of both tubes and ovaries The patient made a very rapid recovery

Pathological Condition —The uterus, after hardening, measured 4×4×4½ in, and was symmetrically enlarged, the wall of the fundus was 2 in thick The cut surface was fibrous and numerous small cavities were scattered throughout Many of these cavities were subperitoneal and some of them contained dark blood On the upper and posterior surface was a roughened area where the intestines were adherent There was one small fibroid in the posterior wall of the fundus, and the endometrium appeared thickened and ragged Both tubes were small and appeared normal The ovaries were slightly enlarged and contained several cysts which were filled with a clear straw-coloured fluid Attached to the wall of two of these cysts was some old blood-clot Microscopical section showed in the endometrium numerous glands with regular and single-layered epithelium The stroma was relatively scanty, and there was no evidence of inflammatory reaction The endometrium seemed to be spreading deeply into the muscular wall Sections of the uterine wall showed slight increase of fibrous tissue, and all sections showed the uterine wall to be infiltrated with islands of tissue indistinguishable from the endometrium Some of the gland spaces were filled with blood, especially those near the peritoneal surface Sections of the ovaries gave no evidence of endometrioma and no lutein tissue was to be seen

In most of the specimens of diffuse adenomyoma which had been reported, said Dr Burns, the adenomyomatous condition had been described as a tumour or tumours localised to some portion of the uterine wall In this specimen the whole uterine wall appeared to be permeated with the endometrial tissue, and he suggested that this was a true endometriomatosis

Prof. Miles Phillips (Sheffield) asked if the condition was associated with pain, if there was definite evidence of downgrowth from the surface of the endometrium, and if any communication could be made out between any of the spaces and the cavity of uterus

Dr Burns replied that there was no pain and no microscopical evidence of downgrowths of endometrium

Dr Leith Murray (Liverpool) described a case of

Suppuration in a Pseudomucinous Cyst

The one now recorded, he said, was the only case of suppuration that he had seen in a consecutive series of 115 pseudomucinous cysts The rarity of the complication was interesting in view of the fact that fluid from such cysts had been, in the past at least, recommended for use in certain culture media

A woman, aged 34, was admitted to hospital in March, 1926, with a history of swelling of the abdomen since the birth of her second child seven months previously, there had been a more rapid development in the two months preceding her admission, but pain had been completely absent

On *examination* the patient was obviously in a condition approximating to the typhoid state, she had a dry, furred tongue, dilated pupils, and a temperature ranging from 100°–103° F As her pulse-rate was 90 to 100 it was thought inadvisable to operate until a Widal reaction had been taken, this proved negative for typhoid and paratyphoid A and B A blood-count showed 16,875 leucocytes per c mm There was a slight trace of albumin in the urine and a moderate amount of pus The abdomen showed a tense cystic swelling reaching to midway between the umbilicus and the ensiform cartilage, it was not in the least tender and the abdominal wall moved freely over it

Operation —Although it appeared unlikely that a cyst which was mobile and not at all tender was the cause of so much general upset, it was finally decided to operate A cyst weighing 9 lb 6 oz was removed through a vertical incision There was hardly any ascites and only one small (½ in) adhesion to the small intestine While this piece of gut was being separated there was a slight leakage of purulent material A dab was promptly placed over the spot, the cyst was delivered entire as rapidly as possible, and the abdomen was completely closed

The patient's temperature was normal next day, and remained so during an uninterrupted convalescence The improvement in her appearance was dramatically rapid

The *specimen* showed a typical pseudomucinous cyst of the right ovary with one large loculus containing more than a pint of creamy pus approaching the surface at the point where the intestine had been adherent, the rest of the cyst appeared to be uninfected The contrast between the large purulent loculus and the clear pseudomucin in the smaller loculi was very marked There was no twist of the pedicle Cultures, both aerobic and anaerobic, proved sterile after 48 hours, nor were any bacteria observed in direct films of the pus Pseudomucin was present both in the pus and in the non-infected loculi, and the microscopical structure was as usual, except around the abscess cavity where only traces of epithelium were observed and round celled deposit was intense

The interest of the case, said Dr Murray, lay in the history of normal labour and in the very small size of the intestinal adhesion Bland-Sutton[1] had observed that it seemed somewhat difficult to understand how ovarian cysts could become inflamed, enclosed as they were in air-tight cavities, and having no communication with other organs He considered the principal sources of infection to be the Fallopian tubes, the intestines, the appendix, and "tapping" To these must be added,[2] as was proved by several cases of typhoid infection of ovarian cysts, infection by the blood stream in systemic diseases of infective origin Pfannensteil[3] expressed the opinion that infection of an ovarian cyst was usually derived from the tube or intestine—the latter almost exclusively when the cyst was adherent to bowel or even near it if the bowel was injured or damaged from any cause

A discussion of the case followed in which the President, Prof Phillips, and Prof Henry Briggs (Liverpool) took part

Dr N E Edwards (Manchester) described a case of

Rupture of the Uterus

A woman, aged 36, had had four previous labours—first, instrumental, second, breech, third, instrumental, and fourth, normal delivery three years ago The pelvis was slightly contracted and of rachitic flat type

Labour pains began at 5 A M on Sept 30th Membranes ruptured at 11 A M., and the doctor was then of opinion that the breech presented Pains increased until 4 P M.—11 hours after onset—when they suddenly ceased, being replaced by continuous pains in abdomen, back, and right shoulder, associated with vaginal hæmorrhage The patient was admitted to hospital with moderate collapse, a temperature of 97 4° F, and a pulse-rate of 120, she had a trace of albuminuria. Abdominal examination revealed the fœtus lying transversely with its head in the mother's right flank free in peritoneal cavity The contracted uterus was felt lying over to the left side No presenting part was to be felt on vaginal examination.

Dr Brentnall opened the abdomen and removed from the peritoneal cavity a female fœtus (9½ lb), with its placenta In the lower segment of the uterus there was a complete transverse rupture which began just in front of the right uterine artery and ended behind the left uterine artery, which was severed Supravaginal hysterectomy was performed at the level of the rupture, a drainage-tube was put in the pouch of Douglas, and intravenous saline was given The patient recovered after somewhat stormy convalescence.

Discussing the cause of the rupture, Dr Edwards pointed out that there had been no interference by doctor or midwife He attributed the accident to repeated childbearing at short intervals, associated probably with some injuries to the lower uterine segment by instruments, these having given rise to muscular atrophy and fibrosis One of these weak spots had given under the strain caused by the vigorous attempts of the uterus to expel a large child through a relatively small pelvis The presentation might have been a breech with extended legs It must also be considered what part had been played by toxæmia, as evidenced by albuminuria

Dr J W A Hunter described

An Unusual Case of Local Peritonitis following Ectopic Gestation

History —The patient was a woman of 34 On Dec 17th her doctor was called on account of sudden acute abdominal pain with vomiting and slight bleeding from the vagina Some slight fullness was felt in the pouch of Douglas, which was tender on pressure, this was attributed to a retroverted gravid uterus The temperature was normal, and the pulse-rate 90 She admitted being 14 days over her time.

[1] Bland-Sutton Diseases of the Ovaries and Tubes

[2] Taylor Typhoid Infection of Ovarian Cysts, Journal Obst and Gyn Brit Emp, 1907, xii, 367

[3] Pfannensteil Quoted by Tayor vide supra

On the following day she was much better and went about her daily routine but on the third day there was a recurrence of abdominal pain, and an increase in pallor, and the pulse-rate rose to 100 On the fourth day she was still doing her work and her condition was unchanged

On the morning of the fifth day her symptoms rapidly became more severe Her doctor was called in and found her complaining of still greater abdominal pain On examination the abdomen was more tender than before, the pulse-rate was 110, and for the first time the temperature rose above normal and was 100° F In the evening she was even worse, the abdomen was distended, very tender and rather rigid The temperature had risen to 102°, the pulse-rate was 130, and on examination the doctor noticed, for the first time, a profuse and very foul-smelling vaginal discharge. She was then sent into St Mary's Hospital

On admission the patient was extremely pale and rather collapsed. The tongue was dry and brown, and there was sordes on the lips The temperature was 104°, and pulse-rate 124 The abdomen was distended and very tender, especially in the lower part, and percussion showed the presence of free fluid in the flanks A foul and dirty brownish discharge was coming from the vulva, and vaginal examination revealed signs of early pregnancy with fullness and tenderness in all the fornices In both posterolateral fornices tender adherent swellings were felt, similar to those usually palpable in acute salpingitis, and giving the impression of acute adnexal inflammation A diagnosis of pelvic peritonitis complicating early pregnancy was made, and laparotomy was decided upon as the infection appeared to be spreading to the upper part of the peritoneal cavity.

Operation (Dec 22nd) —A small mid-line incision was made above the pubes. It was difficult to recognise the peritoneum, for when it was reached dark-brown fluid and bubbles of gas could be seen through it, so that there was some hesitation about opening it because it resembled bowel On incising the peritoneum there was an escape of gas, followed by a large quantity of dark-brown, very foul-smelling fluid which had been distributed throughout the peritoneal cavity In this fluid were some pieces of disintegrating blood-clot When a hand was inserted into the pelvis the pouch of Douglas was felt to be obliterated by adhesions, and both appendages were bound down, so a tube was put down into the pelvis and the abdomen closed, no further treatment being thought advisable

On the following day the temperature came down to normal but rose to 102° in the evening, it again became normal on the third day, the patient being very much better On the fourth day the temperature rose to 100° and she was not so well. Thereafter improvement ceased; the abdomen became hard and distended with obvious general peritonitis, and on the ninth day after operation she died.

Post-mortem examination revealed a large purulent subphrenic abscess There was a small tubal gestation in the isthmic portion of the right tube Obviously this ruptured at the time when the symptoms began, and a hæmatocele formed in the pouch of Douglas Five days later this became infected, as shown by the sudden onset of temperature and signs of pelvic peritonitis

The interesting questions in this case, said Dr Hunter were, Was the infection due to a gas-forming organism, or was the gas, present in the peritoneal cavity, due to septic disintegration of blood-clot? Probably to the latter, for after operation there was no further sign of gas-formation and at autopsy the subphrenic abscess was of the ordinary pyogenic variety Secondly, what had been the starting-point of the infection? Was it from the bowel or from the vagina? Probably it was vaginal, otherwise it was difficult to explain the profuse and foul vaginal discharge No evidence of interference could be obtained though this was suspected, but the patient had admitted that she knew herself to be pregnant, and was known to have brought on an abortion herself about a year ago

Prof D DOUGAL said that he thought the gas was due to infection of the blood-clot He had seen a case of infection by *Bacillus aerogenes capsulatus* in which the uterus and the fœtus therein showed gas spaces and grew cultures of this organism

Miss FRANCES IVENS (Liverpool) showed a specimen of squamous carcinoma of the clitoris, associated with a cyst of the broad ligament, in a woman of 84, and a specimen of mixed-celled sarcoma of the ovary with pelvic tuberculosis

Reviews and Notices of Books.

ACUTE SEPTIC CONDITIONS IN SURGERY

Die Akuten Eitrigen Infektionen in der Chirurgie und ihre Behandlung. By Dr. ARTHUR BUZELLO. Privat docent and Assistant to the Surgical Clinic at Greifswald Berlin: Urban and Schwarzenberg 1926 Illustrated Pp 495 M 30

IT is to be supposed that this unusual classification of surgical diseases was adopted because so often septic cases are segregated in hospitals It is of doubtful advantage to group clinical cases according to their bacterial origin, but Dr Buzello has performed his self-imposed task very creditably. The volume is divided into a general part in which the behaviour of the body to infection, the natural history of septic organisms and methods of treatment such as vaccine therapy, auto-pyotherapy,

A special part follows which makes interesting reading, since the methods practised in Greifswald can be contrasted with those used in this country. Thus we find that he recommends the excision of facial carbuncles in order to save life and to lessen subsequent scarring, he also recommends the excision of ordinary carbuncles, without subsequent suture. Dr Buzello has obtained good results by the injection of the patient's own blood into the tissues surrounding a carbuncle In the section on panaritium he recommends what amounts to excision of small subcutaneous whitlows Healing of the frequent horseshoe incision of the terminal phalanx can be promoted by strapping the flap back into place when granulations appear—a useful hint When the tendon is lost in a finger, function of the digit will be lost also, and the author thinks early amputation of such useless fingers is advisable and rational, but never should such a course be followed when the thumb is the digit infected. Bier's treatment he finds useful in septic joints, but always combined with frequent aspiration, since it is no good to persist when frank pus has formed In mildly infected joints he washes out the cavity with 5 per cent. carbolic or injects 20 per cent iodoform in glycerine There is no mention of Willem's mobilisation treatment for a septic knee-joint As a prophylactic measure against infection after operating upon a knee-joint for some internal disorder, a plaster bandage is always applied In septic peritonitis irrigation is still used in early stages Opium is said never to be given in peritonitis, though a few pages later morphine is recommended for vomiting in this condition Every effort is directed to getting the bowels to act and a hot-air bath is said to be very effective for this purpose Breathing exercises after septic abdominal operations seem to be a good recommendation Actinomycosis is included amongst the septic diseases, as also is tetanus

The last section of the book describes the general septic diseases, septicæmia, pyæmia, and sapræmia, with methods of investigation and treatment The weakness of the method of classification adopted in this book is exemplified by the fact that such important septic surgical conditions as lateral sinus thrombosis, frontal sinus suppuration, and brain abscess are not described.

ELECTROTHERMIC METHODS IN THE TREATMENT OF NEOPLASTIC DISEASE

By J DOUGLAS MORGAN, B A, M D, Assistant Radiologist, Philadelphia General Hospital Philadelphia F. A. Davis Company. 1926. Pp 172 10*s* 6*d*

THE electrothermic methods of surgery are those in which high-frequency currents are used to generate heat within the body for the purpose of destroying or excising morbid tissue There are various ways of utilising the currents for these purposes The author devotes most space to the mode of treatment known as electrodesiccation. In this the heat is insufficient to cause actual coagulation of tissue, but is able to deprive it of water The author describes the principles of the method and the way of performing the operation He points out the beneficial results which can be obtained in the treatment of superficial malignant growths and benign tumours and other forms of morbid tissue According to the description the extent of desiccation is within full control of the operator Dr Morgan says that the results following the process are so perfect that a carcinoma involving the edge of an eyelid, the inner canthus of an eye, the tonsils or the larynx may be completely destroyed without impairing either the appearance or function of the part involved He also gives an account, under the heading "electrocoagulation," of the method known to European workers as "diathermic coagulation" or "surgical diathermy" The technique, and the results which may be expected in the treatment of malignant tumours in certain regions are described There is also a brief reference to the use of high-frequency currents for cutting tissue and excising tumours. The book contains chapters on first principles and the meaning of terms, on the chemical and physical properties of currents, on apparatus, and on the history of surgical diathermy The author deplores the abundance of terms employed by different writers for the description of the same treatment and refrains from the temptation of adding to the list

It is likely that the English reader will be most interested in the description of electrodesiccation This form of treatment seems to be popular in America, but it has not yet been adopted by workers in this country There is no precise information which will enable those who have not practised the method to ascertain when the tissue is desiccated Does it change its appearance, colour, or consistency? The monograph forms a clear introduction for those who desire to learn the important part played by electrothermic methods in surgery at the present day The pages are well printed in large type and a number of helpful illustrations are included

PSYCHOTHERAPY IN THE INSANE.

Selbstschilderungen der Verwirrtheit Die Oneiroide Erlebnisform By Privatdozent Dr W. MAYER-GROSS, Assistant Physician to the Psychiatric Clinic, Heidelberg Berlin Julius Springer Pp. 296. M. 219

THIS monograph, one of the voluminous Foerster-Wilmanns series on neurology and psychiatry, deals with the most difficult and debatable part of all psychological medicine, which is to evolve a system of diagnostics and therapeutics from what many are content to call the patient's "ravings." Freud, Jung, and Adler and their disciples have based systems of diagnosis and cure on the analysis of their patients' minds, and although they are opposed by considerable scepticism there is good evidence that their methods succeed in relieving many neurotic conditions They, however, are dealing with what the world calls "sane" patients, who, for all their ailments, know what they are talking about and can cooperate in the process Dr Mayer-Gross, a psychiatrist of great repute, has set himself the infinitely more difficult task of reading a meaning into the phantasies, delusions, and ramblings of patients suffering from advanced functional psychoses He sees in these distorted fragments of mental expression the causes that have distorted the mind, and sometimes the means that will counteract them He is not advocating a system based on speculation but one that he is testing every day in his own clinic It is not intended to replace the existing means but to supplement them, and no one will deny that they need supplementing His book consists of the verbatim records of the accounts of their subjective experiences given by eight patients suffering from various psychoses of biogenic origin together with the author's analysis, comments, and deductions His section on the acute hallucinatory psychosis is especially interesting (p 170), for his results suggest to him several new theories of the pathology of this condition Not many people in England will read this book, but its work will be done if it inspires an English psychiatrist to publish the results of his own investigations along similar lines

THE ENLARGED PROSTATE

By KENNETH M WALKER, F R C S, M A., M B, B C, Lecturer in Venereal Diseases, St Bartholomew's Hospital, Surgeon with Charge of Genito-Urinary Department, Royal Northern Hospital; Surgeon to St Paul's Hospital London Oxford University Press, Humphrey Milford. *1927 Pp 193 12s 6d*
